Abstract

Modern statistical experiments routinely feature a large number of input variables that can each be set to a variety of different levels. In these experiments, output response changes as a result of changes in the individual factor level settings. Often, an individual experimental run can be costly in time, money or both. Therefore, experimenters generally want to gain the desired information on factor effects from the smallest possible number of experimental runs. Orthogonal arrays provide the most desirable designs. However, finding orthogonal arrays is a very challenging problem.

There are numerous integer linear programming formulations (ILP) in the literature whose solutions are orthogonal arrays. Because of the nature of orthogonal arrays, these ILP formulations contain symmetries where some portion of the variables in the formulation can be swapped without changing the ILP. These symmetries make it possible to eliminate large numbers of infeasible or equivalent solutions quickly, thereby greatly reducing the time required to find all non-equivalent solutions to the ILPs.

In this dissertation, a new method for identifying symmetries is developed and tested using several existing and new ILP formulations for enumerating orthogonal arrays.
For my Dad, who always taught me the value of learning.
Acknowledgments

I would like to sincerely thank my advisor, Dr. Dursun Bulutoglu, for his countless hours of hard work and dedication. He went above and beyond at every turn to ensure the success of this research effort.

This research was supported by the AFOSR grant F1ATA03039J001.

DIFFERENT FORMULATIONS OF THE ORTHOGONAL ARRAY PROBLEM AND THEIR SYMMETRIES

I. Introduction

1.1 Motivation

Since the discovery of the scientific method in the 17th century, the analysis of experimental results has been the mechanism through which virtually all hypotheses have been tested. Montgomery [26] defines an experiment as “a test or series of runs in which purposeful changes are made to the input variables of a process or system so that we may observe and identify the reasons for changes that may be observed in the output response.”

Here in the early 21st century, human knowledge and technology have advanced so far that today’s experiments routinely feature a large number of input variables (commonly called factors) that can each be set to several different levels. In these experiments, the output response changes as a result of changes in the individual factor level settings. One can easily see that for most modern experiments, conducting a full factorial design experiment, where all possible combinations of all factor levels are tested, can be too difficult to conduct either due to cost or time constraints. One prominent way to obtain the required output responses from an experiment at a lower cost than a full factorial experiment is to design an experiment, such as a fractional factorial design [26]. A fractional factorial design is essentially a subset of a full factorial design experiment where only a fraction of the runs are used. The fraction is selected to make optimal use of the sparsity-of-effects principle to isolate out the main effects and interactions of interest [26].

Fractional factorial designs have been used for product development and testing in industry for decades with great success. In particular, these designs have been used by
the United States Department of Defense to both improve the quality of weapons systems and other equipment as well as to lower maintenance, operation and replacement costs. The United States Air Force (USAF) is particularly dedicated to this type of testing and evaluation. The USAF operates a number of test and evaluation centers that examine and evaluate the full spectrum of its systems and equipment. These centers use designed experiments to test aircraft, motor vehicles, communication networks, avionics, radars, lasers, computer systems, automated information systems, directed energy weapons, ordinance, missiles, air traffic control systems, aircraft landing systems, reconnaissance platforms, nuclear weapons systems, weather sensors and space systems to name a few. These tests provide engineers with the data needed to make valid inferences about the capabilities of equipment and systems in order to improve quality and performance. More in-depth discussions of these types of tests conducted by the USAF test and evaluation community can be found in Tucker et al. [33], Hill and Chambal [14] and Hutto and Higdon [16]. It is clear from the level of effort put into testing and evaluation by the USAF that there is a need for efficient large-scale factorial designs to ensure that increasingly complex USAF systems operate at their peak of efficiency for the lowest possible cost.

When looking at costs, the USAF is not just concerned with evaluating the life cycle cost of its systems and equipment. The cost of testing and evaluation is also of great concern, particularly in times of shrinking federal budgets. As previously discussed, conducting test runs of factor level combinations can be very expensive and often a full factorial design experiment is prohibitively expensive. For example, the test of a particular missile system may cost several million dollars per missile test. In these cases, fractional factorial designs are best used to determine optimal operational factor settings. A properly selected fractional factorial design is critical if one wishes to obtain as much pertinent
information as possible at a fixed cost. It is well known that orthogonal arrays can serve as the paragon of efficient fractional factorial designs.

An Orthogonal Array (OA) with strength $t$ is an array consisting of elements drawn from a fixed, finite set of symbols that are arranged in such a way that for every $t$ columns of the array, all ordered $t$-tuples of the symbols appear an equal number of times. In statistical experiments, a factorial design $\mathbf{D}$ with $N$ runs, $k$ factors, and $s$ levels is an OA of strength $t$, where $1 \leq t \leq k$, if each of the $s^t$ $t$-level combinations appear exactly $\lambda = N/s^t$ times when $\mathbf{D}$ is projected onto any $t$ factors. The integer $\lambda$ is called the index of the OA. Such an OA is usually referred to using the shorthand $\text{OA}(N, k, s, t)$. Xu and Wu [35] showed that, under the hierarchical ordering principle of factorial effects, a factorial design with a Generalized Wordlength Pattern (GWP) that is lexicographically smaller is more desirable. Hence, OAs with the Generalized Minimum Aberration (GMA) (designs that sequentially minimize the GWP criterion) are the most desirable designs. Finding such orthogonal arrays remains a very challenging problem.

OAs have additional applications outside the realm of designed experiments. In the 2012 U.S. Defense Strategic Guidance, the Secretary of Defense listed the ability to “operate effectively in cyberspace and space” as one of the primary missions of the U.S. Armed Forces [28]. In that same document, the Secretary further emphasized the need to build on advancements in network warfare and capitalize on the interconnected nature of every individual and piece of equipment on the modern battlefield [28]. As such, it is obvious that U.S. military information networks will only continue to grow in the future. In an unpredictable and fast-moving combat environment, network reliability will become essential to mission effectiveness. OAs can be used to assist in maintaining the security of these vital networks. In particular, Fecko and Steinder [10] demonstrated that 3-level OAs can be used for multiple fault localization in an unreliable environment like a modern battlefield. In their research, OAs were able to reduce the exponential number
of failure configurations in a battlefield network to a small enough subset that statistical analysis could be performed to locate the likely causes of failures. The ability to efficiently and accurately generate OAs would be of great use to a wide variety of research and testing organizations within the USAF as well as to the larger scientific and engineering community.

1.2 Research Contribution

The next chapter provides a review of recent best efforts to develop algorithms that generate GMA OA\((N, k, s, t)\) for many values of \(N, k, s\) and \(t\). These algorithms generate OAs by enumerating all solutions of different ILP formulations. The research in this dissertation seeks to build upon the current ILP-based algorithms for finding GMA or near-GMA OAs in Bulutoglu and Margot [7], Bulutoglu and Ryan [8] as well as new formulations developed from results in Rosenberg [29], Williamson [34] and Seberry and Yamada [31]. It features a thorough investigation of proposed enhancements to the best known algorithms for finding GMA OA\((N, k, s, t)\). These enhancements are based on a generalization of the symmetry group of a Linear Program (LP) in Margot [23].

In Chapter 3, it is shown that there are no redundant inequalities in the LP relaxation of the Rosenberg [29] ILP that describes OA\((N, k, s, t)\)s. This implies that each inequality is a facet of the LP relaxation. In Section 3.3, this result is used to determine the order of the symmetry group of the LP relaxation of the Rosenberg [29] ILP. The practical value of this result is that it exhibits the shortcomings of the Rosenberg [29] ILP LP relaxation symmetry group in describing the symmetries of the OA problem.

Bulutoglu and Margot [7] previously proved that the isomorphism group, the group that sends OAs to OAs by permuting factors or levels within each factor, is a subgroup of the ILP automorphism group that they used to enumerate OAs. Based on computational observations, they conjectured that these two groups are equal. This conjecture is proved in Chapter 3.
In Section 4.2.1, for many $N, k, s, t$ combinations, the Margot ILP solver [22] is used to find a set of all non-isomorphic solutions to the Rosenberg [29] ILP by exploiting the symmetry group of its LP relaxation. For the same $N, k, s, t$ combinations, this is compared to finding all non-isomorphic solutions to the Bulutoglu and Margot [7] ILP formulation by exploiting the larger isomorphism group. In most cases, enumerating a set of all non-isomorphic solutions to this ILP is faster, even though it has more variables. This provides a plethora of ILPs where exploiting a larger symmetry group more than overcomes the additional burden of having a larger number of variables. This is significant since it is contrary to the preprocessing step in mathematical programming that calls for deleting as many variables as possible from an ILP formulation.

It is essential to find larger subgroups of the ILP’s symmetry group to speed up the Margot ILP solver [22] enumeration. The Margot ILP solver [22] uses the automorphism group of the formulation. This group is equal to the symmetry group of the LP relaxation, if the LP relaxation has no redundant inequalities and is full dimensional. Otherwise, a non-full dimensional LP relaxation may contain hidden symmetries not captured by the formulation automorphism group.

Section 4.2 results suggest that converting an ILP with inequality constraints into an equality constrained ILP by adding slack integer variables can be beneficial if one is to use the Margot ILP solver [22]. This, in turn, underscores the importance of finding larger subgroups of the symmetry group of an ILP with equality constraints. Currently, the Margot ILP solver [22] exploits the automorphism group of the ILP formulation. This group is always a subgroup of the LP relaxation symmetry group. Thus, it is more desirable to exploit the LP relaxation symmetry group. The LP relaxation of an ILP with equality constraints is not full dimensional. Hence, there is a need for algorithms that find the symmetry group of a general linear program with equality constraints. In Sections 4.2 and 4.3, an algorithm is developed that satisfies this need. This is the first time
in the literature that an algorithm for finding the symmetry group of a non-full dimensional linear program is developed.

In Section 4.2, the developed algorithm is implemented on LP relaxations of ILPs with equality constraints that describe orthogonal arrays. Computational results reveal previously unknown hidden symmetries of the Bulutoglu and Ryan [8] ILP formulation of the OA problem. Consequently, exploiting the newly found symmetries decreases solution times significantly.

In Section 4.3, the newly developed algorithm is tested with the LP relaxation symmetry groups of modified versions of Mixed Integer Linear Programs (MILPs) featured in Liberti [18]. It reveals hidden symmetries of the modified MILPs that could not otherwise be detected.

In general, the symmetry group of an ILP contains the symmetry group of its LP relaxation. One fundamental question is: “How close is the LP relaxation symmetry group to capturing all the symmetries in the ILP?” In Section 4.4, attempts are made to answer this question for the OA problem. This is accomplished by calculating the symmetry group of the Bulutoglu and Ryan [8] ILP, for several OA($N,k,s,t$).

In Section 4.5, attempts were made to speed up the Bulutoglu and Ryan [8] OA extension algorithm by exploiting the LP relaxation symmetry groups of various formulations.

In Section 5.2, some open problems resulting from the research in this dissertation are presented. In Section 5.3, several conjectures are made based on the Chapter 4 computational research results. In Section 5.4, several follow-up computational projects are proposed.

1.3 Organization of Dissertation

This dissertation is organized into five chapters and two appendices. Chapter 2 provides a review of recent publications that have directly lead to the study of the
research problem discussed in this dissertation. Chapter 3 discusses theoretical work derived from the literature review. Chapter 4 discusses the four computational research objectives. Chapter 5 provides a list of conjectures and research directions for future efforts. Appendix A contains part of the computer code that was used to achieve the results in Chapters 2 and 3. Finally, Appendix B contains the computer code that was used to achieve the computational research results in Chapter 4.
II. Literature Review

2.1 Chapter Introduction

This chapter first discusses various methods that have been developed to generate OAs using ILPs. It then presents background material on permutation groups. This is followed by an explanation of the relationship between permutation groups as symmetry groups of OA-generating ILPs and isomorphisms of OAs. This leads to a discussion of how to find large subgroups of the symmetry groups of ILPs more efficiently. The chapter concludes with a summary of the solver developed by Margot [22] that takes advantage of symmetry groups of ILPs to more rapidly enumerate solutions.

2.2 ILPs That Generate OAs

One efficient and effective approach to generating OAs is to formulate an ILP whose feasible set is the set of all OA($N, k, s, t$). If the ILP has no feasible solution, then an OA($N, k, s, t$) does not exist.

Rosenberg [29] proved the following Lemma.

Lemma 1. Define a sequence \( \{a_c\} \) recursively by

\[
a_0 = \lambda, \quad a_c = \lambda - \sum_{e=0}^{c-1} a_e \binom{k-t}{c-e} (s-1)^{c-e} \quad \text{for} \quad c \geq 1.
\] (2.1)

Let \( \mathbf{z}, \mathbf{x} \) and \( \mathbf{y} \in \{1, \cdots, s\}^k \) be row vectors with \( 0 \leq d(\mathbf{z}, \mathbf{x}) \leq t \) where \( d(\mathbf{z}, \mathbf{x}) \) is the number of non-zero entries in \( \mathbf{z} - \mathbf{x} \). Also, let \( I_x = \{i \in \{1, \cdots, k\} : x_i \neq z_i\} \) and \( J_x = \{y \in \{1, \cdots, s\}^k : y_i = x_i \ \forall i \in I_x\} \). Then

\[
N_x = a_{t-d(\mathbf{z}, \mathbf{x})} + (-1)^{t-d(\mathbf{z}, \mathbf{x})+1} \sum_{y \in J_x, d(\mathbf{z}, y) > t} \binom{d(\mathbf{z}, y) - d(\mathbf{z}, \mathbf{x}) - 1}{t - d(\mathbf{z}, \mathbf{x})} N_y,
\] (2.2)

\( N_y \geq 0 \), for \( y \) such that \( d(\mathbf{z}, y) > t \),
where \( N_x, N_y \) are the number of times factor level combinations \( x, y \) appear in a conjectured \( OA(\lambda s^t, k, s, t) \).

If we are given the values of \( N_x \) for every \( x \in \{1, 2, ..., s\}^k \) where \( d(x, z) > t \), then equation (2.2) has at most one integer solution with \( N_x \geq 0 \) for the remaining \( N_x \)'s. The system of linear equations in equation (2.2) can be viewed as the constraints of an ILP with equality constraints, where the objective function \( c^T x \) is chosen to be zero. All feasible solutions of this ILP are the indicator vectors of all \( OA(N, k, s, t) \).

In a separate effort, Appa et al. [3] examined two different ways to use a combination of constraint and integer programming to find \( p \times p \) Orthogonal Latin Squares (OLS) for \( 3 \leq p \leq 12 \) and three \( p \times p \) Mutually Orthogonal Latin Squares (MOLS). In terms of the notation used here, \( k p \times p \) MOLS correspond to an \( OA(p^2, k + 2, p, 2) \). Appa et al. [2] successfully used an ILP formulation to generate \( p \times p \) OLS's for \( 4 \leq p \leq 5 \) and \( 7 \leq p \leq 12 \). Additionally, they proved that \( 6 \times 6 \) OLS do not exist.

Without the knowledge of Lemma 1 in Rosenberg [29], Bulutoglu and Margot [7] used an ILP formulation to enumerate OAs. They defined \( D_{s^t} \) to be the full factorial design where each run is treated as a base-\( s \) integer and placed in lexicographical order. They then defined the indicator vector \( x \) where every \( x_i \) is the number of times the \( i \)th run of \( D_{s^t} \) appears in a particular \( k \)-factor, \( s \)-level fractional factorial design \( D \). Next, they defined a set \( T \) of \( s^t \times s^k \) matrices obtained by taking the Kronecker products of \( t I_s \)'s and \((k - t)I_s\)'s in every possible order, where \( I_s \) represents the \( s \times s \) identity matrix and \( 1_s \) is an \( s \times 1 \) vector of 1's. As such, \(|T| = \left(\begin{array}{c} k \\ t \end{array}\right)\) and every matrix \( A_j \in T \) has the form

\[
A_j = M_{1j} \otimes M_{2j} \otimes \ldots \otimes M_{kj}
\]

where \( 1 \leq j \leq |T| \) and \( M_{ij} \in \{ I_s^T, 1_s \} \). Finally, they observed that for the set \( L_j = \{ i_{1j}, i_{2j}, ..., i_{sj} \mid M_{ij} = I_s \} \), \( A_j x = \lambda 1_s \) if and only if when \( D \) is projected onto the factors indexed by \( L_j \), all \( s^t \) factor level combinations appear exactly \( \lambda \) times. This means that a solution to

\[
A_j x = \lambda 1_s \text{ for } x \geq 0 \text{ for } j = 1, 2, ..., \left(\begin{array}{c} k \\ t \end{array}\right)
\]
is integral if and only if $\text{OA}(N, k, s, t)$ exists and that each integer solution identifies an $\text{OA}(N, k, s, t)$ [7].

Let $r_{\text{max}}$ be the maximum number of times a factor level combination can appear in an $\text{OA}(N, k, s, t)$ then Lemma 5 in Bulutoglu and Margot [7] implies $r_{\text{max}} \leq p_{\text{max}}$, where

$$
p_{\text{max}} = \max Y_0
$$

$$
\text{s.t.} \quad \sum_{i=h}^{k} \binom{i}{k} Y_{k-i} = \lambda s^t \binom{k}{h} \quad \text{for} \quad 0 \leq h \leq t,
$$

$$
Y_i \in \mathbb{Z}_{\geq 0} \quad \text{for} \quad 0 \leq i \leq k.
$$

The computer code that they used to find $p_{\text{max}}$ was also used in this dissertation.

Letting $1_{(t)}s^t$ be the $\binom{t}{i}s^t \times 1$ vector of 1’s and $A(k, s, t)$ be the $\binom{t}{i}s^t \times s^k$ matrix

$$
A(k, s, t) = \begin{bmatrix}
A_1 \\
A_2 \\
\vdots \\
A_{\binom{t}{i}}
\end{bmatrix}
$$

then Theorem 2 in Bulutoglu and Margot [7] implies that the set of all solutions to the ILP

$$
\min 1_s^T x
$$

$$
\text{s.t.} \quad A(k, s, t)x = \lambda 1_{(t)}s^t
$$

$$
x \in \{0, 1, 2, \ldots, p_{\text{max}}\}^{s^k}
$$

is precisely the set of indicator vectors for all $\text{OA}(N, k, s, t)$. In ILP (2.4) the objective function $1_s^T x$ was introduced only for convenience and is equal to $N$ for every feasible solution.
Bulutoglu and Ryan [8] provided a more efficient version of this ILP that has only
\[ \sum_{q=0}^{t} (s-1)^q \binom{k}{q} \] equality constraints with no redundant constraints:

\[
\min \quad 0 \\
\text{s.t.} \quad \sum_{(i_1,\ldots,i_k)\in\{0,\ldots,s-1\}^k} x_{[\sum_{j=1}^{q}s_{[j]}i_{[j]}=1]} = \frac{N}{s^q} \quad \text{for each subset of } q \text{ indices } \{i_{j_1}, i_{j_2}, \ldots, i_{j_q}\},
\]

for \( q = 0, \ldots, t \) and

\[
x_1 \geq 1, \quad x \in \{0, 1, 2, \ldots, p_{\text{max}}\}^k.
\]

The constraint \( x_1 \geq 1 \) in ILP (2.5) ensures that \((0, 0, \ldots, 0)\) appears at least once and helps the solver find feasible solutions faster [8]. Using 0 as the objective function also speeds up the enumeration process. The algorithm in Figure 2.1 summarizes how to utilize ILP (2.5) to enumerate all OA(\(N, k, s, t\)).

\begin{figure}[h]
\begin{algorithmic}
1. Input \(N, k, s\) and \(t\). Let \(T = \emptyset\).
2. Determine \(p_{\text{max}}\) using ILP (2.3).
3. Find the set of all feasible solutions \(X\) to ILP (2.5).
4. For each solution \(x_q \in X\),
   \begin{enumerate}
   \item Let the factor level combination \((i_1, \ldots, i_k)\) appear in \(T_q x_{[\sum_{j=1}^{q}s_{[j]}i_{[j]}=1]}\) many times.
   \item Set \(T = T \cup T_q\).
   \end{enumerate}
5. Return \(T\).
\end{algorithmic}
\caption{Improved Bulutoglu and Margot ILP [8] Based Algorithm}
\end{figure}

An additional formulation for strength-2 OAs arises from Hadamard matrices. A Hadamard matrix is an orthogonal \(N \times N\) matrix with entries that are either -1 or +1.
For any \( n \in \mathbb{Z}_{\geq 0} \), \( \text{OA}(4n, 4n-1, 2, 2) \) exist if and only if there exists a Hadamard matrix of order \( 4n \) [13]. This is true because deleting the column of all +1’s from a \( N \times N \) Hadamard matrix, results in an \( \text{OA}(N, N-1, 2, 2) \) where the levels are coded as -1 and +1 (Hadamard matrices exist only if \( N \) is divisible by 4).

Williamson [34] defined **Williamson matrices** to be any four \( n \times n \) circulant matrices \( W_1, W_2, W_3 \) and \( W_4 \) with entries equal to -1 or +1 such that

\[
W_1^2 + W_2^2 + W_3^2 + W_4^2 = 4nI_n.
\]

Using the Williamson matrices, a \( 4n \times 4n \) Hadamard matrix \( H_{4n} \) is constructed as

\[
H_{4n} = \begin{bmatrix}
W_1 & W_2 & W_3 & W_4 \\
-W_2 & W_1 & W_4 & -W_3 \\
-W_3 & -W_4 & W_1 & W_2 \\
-W_4 & W_3 & -W_2 & W_1
\end{bmatrix}.
\]  

Let \( \omega^j \) be the primitive \( j \)th root of unity and \( \omega_j = \omega^j + \omega^{n-j} \). Williamson [34] showed that Williamson matrices exist if and only if

\[
T_1^2 + T_2^2 + T_3^2 + T_4^2 = 4n
\]

where each \( T_i \) has the form \( 1 \pm 2\omega_{j_1} \pm 2\omega_{j_2} \pm ... \) and each \( \omega_j \) appears only once in only one member of the set \( \{T_1, T_2, T_3, T_4\} \). Noting that \( \omega^j = \cos\left(\frac{2\pi j}{n}\right) + \sqrt{-1} \sin\left(\frac{2\pi j}{n}\right) \) leads to the following theorem:

**Theorem 1.** Let \( \sum_{k=1}^{4} \mu_{k,l}^2 = 4n \) where \( n \) is an odd integer, \( l \mid n \), \( \mu_{k,l} \neq 0 \), and \( \mu_{k,l} = \sum_{i=0}^{\lfloor \frac{n}{2} \rfloor} 4 \cos\left(\frac{2\pi i l}{n}\right) (t_{i2k} - t_{i1k}) \). Williamson matrices of order \( n \) exist if and only if there is at least one feasible solution to the following system of equations in \( t_{ijk} \)

\[
\sum_{k=1}^{4} \mu_{k,l}^2 = \sum_{k=1}^{\lfloor \frac{n}{2} \rfloor} 4 \cos\left(\frac{2\pi i l}{n}\right) (t_{i2k} - t_{i1k})^2 = 4n \text{ for } l \mid n,
\]

\[
\sum_{k=1}^{4} 2 t_{ijk} = 1 \quad \text{for } i = 1, 2, ..., \lfloor \frac{n}{2} \rfloor, \quad j = 1, 2 \text{ and } k = 1, 2, 3, 4.
\]
The nonlinear constraints in equations (2.7) can be linearized as follows. First, using $t_{ijk}^2 = t_{ijk}$, expand the constraints:

$$4n = \sum_{k=1}^{4} \mu_{k, l}^2 = \sum_{k=1}^{4} \left( \sum_{i=0}^{\left\lfloor \frac{n}{4} \right\rfloor} 4 \cos \left( \frac{2\pi il}{n} \right) (t_{i2k} - t_{i1k}) \right)^2$$

$$= 16 \sum_{k=1}^{4} \left( \sum_{i=0}^{\left\lfloor \frac{n}{4} \right\rfloor} \cos^2 \left( \frac{2\pi il}{n} \right) (t_{i2k} + t_{i1k} - 2t_{i2k}t_{i1k}) \right)$$

$$+ 32 \sum_{k=1}^{4} \left( \sum_{\ell' < \frac{n}{4}} \cos \left( \frac{2\pi \ell' l}{n} \right) \cos \left( \frac{2\pi \ell'' l}{n} \right) (t_{\ell'2k}I_{\ell'2k} - t_{\ell'1k}I_{\ell'2k} - t_{\ell''1k}I_{\ell''2k} + t_{\ell''1k}I_{\ell''1k}) \right)$$

(2.8)

Next, let $y_{(i_1,j_1,k_1)(i_2,j_2,k_2)} = t_{i_1,j_1,k_1}t_{i_2,j_2,k_2}$, add constraints $0 \leq t_{i_1,j_1,k_1} + t_{i_2,j_2,k_2} - 2y_{(i_1,j_1,k_1)(i_2,j_2,k_2)} \leq 1$ for each $y_{(i_1,j_1,k_1)(i_2,j_2,k_2)}$ and substitute the $y_{(i_1,j_1,k_1)(i_2,j_2,k_2)}$’s into equalities (2.8). The nonlinear system of equations (2.7) is now written as the linear system of constraints (2.9):

$$4n = 16 \sum_{k=1}^{4} \left( \sum_{i=0}^{\left\lfloor \frac{n}{4} \right\rfloor} \cos^2 \left( \frac{2\pi il}{n} \right) (t_{i2k} + t_{i1k} - 2y_{(i,2k)(i,1k)}) \right)$$

$$+ 32 \sum_{k=1}^{4} \left( \sum_{\ell' < \frac{n}{4}} \cos \left( \frac{2\pi \ell' l}{n} \right) \cos \left( \frac{2\pi \ell'' l}{n} \right) (y_{(\ell'2k)(\ell'2k)} - y_{(\ell'1k)(\ell'1k)} - y_{(\ell''1k)(\ell''2k)} + y_{(\ell''1k)(\ell''1k)}) \right)$$

for $l \mid n$,

$$2y_{(i_1,j_1,k_1)(i_2,j_2,k_2)} - t_{i_1,j_1,k_1} - t_{i_2,j_2,k_2} \leq 0 \quad \text{for each } y_{(i_1,j_1,k_1)(i_2,j_2,k_2)},$$

$$t_{i_1,j_1,k_1} + t_{i_2,j_2,k_2} - 2y_{(i_1,j_1,k_1)(i_2,j_2,k_2)} \leq 1$$

$$\sum_{k=1}^{4} \sum_{j=1}^{2} t_{ijk} = 1 \quad \text{for } i = 1, 2, ..., \left\lfloor \frac{n}{2} \right\rfloor, \ j = 1, 2 \text{ and } k = 1, 2, 3, 4.$$  

(2.9)

Hence, the system of quadratic constraints (2.8) with $4n - 4$ binary variables is turned into a linear system of constraints with $4n - 4 + 4\left\lfloor \frac{n}{2} \right\rfloor + 4\left(\left\lfloor \frac{n}{2} \right\rfloor\right) = (n^2 - 1)/2 + 4n - 4$ binary variables. Combining Theorem 1 and Example 9.1 in Seberry and Yamada [31] leads to the algorithm in Figure 2.2.
1. Let \( n \in \mathbb{Z}_{\geq 0} \), \( N = 4n \), and \( \frac{n}{2} \notin \mathbb{Z}_{\geq 0} \). Let \( \mathbf{U} \) be an empty set of OA(\( N, N-1, 2, 2 \)).

2. Find all solutions to the Binary Integer Linear Program (BILP) (using constraints (2.9)):

\[
\begin{align*}
\text{min} \quad & 0 \\
\text{s.t.} \quad & 4n = 16 \sum_{k=1}^{4} \left( \sum_{i=0}^{\frac{n}{2}} \cos^{2} \left( \frac{2\pi i l}{n} \right) \left( t_{ij} + t_{i1k} - 2y_{(i2k)(i1k)} \right) \
& + 32 \sum_{k=1}^{4} \left( \sum_{i'=1}^{n/2} \cos \left( \frac{2\pi i'l}{n} \right) \cos \left( \frac{2\pi i'q}{n} \right) \right) \right) \text{ for } l \, | \, n, \\
& 2y_{(i1j)(i1j)(i2j)(i2j)} - t_{i1j} - t_{i2j} \leq 0 \quad \text{for each } y_{(i1j)(i1j)(i2j)(i2j)}, \\
& t_{i1j} + t_{i2j} - 2y_{(i1j)(i1j)(i2j)(i2j)} \leq 1 \\
& \sum_{k=1}^{4} \sum_{j=1}^{3} t_{ijk} = 1 \quad \text{for } i = 1, 2, \ldots, \left\lfloor \frac{n}{2} \right\rfloor, \\
& y_{(i1j)(i1j)(i2j)(i2j)} \in \{0, 1\}, \quad t_{ijk} \in \{0, 1\} \quad \text{for } i = 1, 2, \ldots, \left\lfloor \frac{n}{2} \right\rfloor, \quad j = 1, 2, 3, 4.
\end{align*}
\]

(2.10)

3. Let \( \mathbf{Y} \) be the set of all solutions to ILP (2.10) and \( \mathbf{t}_q = \left( t_{ijq} \right) \in \mathbf{Y} \) be the \( q \)th solution to ILP (2.10). Let \( \mathbf{W}_{kq} \) for \( k = 1, 2, 3, 4 \) be the set of Williamson matrices calculated from the solution \( \mathbf{Y}_q \). Also, let \( w_{k,j,q} \) denote the \( j \)th element of the first row of \( \mathbf{W}_{kq} \). Finally, let \( \mathbf{H}_q \) be the \( 4n \times 4n \) Hadamard matrix calculated from the \( \mathbf{W}_{kq} \)’s.

4. For each \( \mathbf{t}_q \in \mathbf{Y} \)

(a) Set \( w_{k,1,q} = 1 \), \( w_{k,j,q} = t_{(j-1),2,k,q} - t_{(j-1),1,k,q} \) and \( w_{k,n-j+2,q} = w_{k,j,q} \) for \( j = 2, 3, \ldots, \left\lfloor \frac{n}{2} \right\rfloor + 1 \) and \( k = 1, 2, 3, 4 \).

\[
\begin{bmatrix}
\begin{array}{cccc}
w_{k,1,q} & w_{k,2,q} & \cdots & w_{k,n,q} \\
w_{k,n,q} & w_{k,1,q} & \cdots & w_{k,n-1,q} \\
\vdots & \vdots & \ddots & \vdots \\
w_{k,2,q} & w_{k,3,q} & \cdots & w_{k,1,q}
\end{array}
\end{bmatrix}
\]

(b) For each \( k = 1, 2, 3, 4 \), \( \mathbf{W}_{kq} = \)

(c) Use equation (2.6) to calculate \( \mathbf{H}_q \) using the \( \mathbf{W}_{kq} \)’s found in previous step. Update \( \mathbf{H}_q \) by removing its first column and set \( \mathbf{U} = \mathbf{U} \cup \{ \mathbf{H}_q \} \).

5. Return \( \mathbf{U} \).

Figure 2.2: Algorithm to Generate OA(\( N, N-1, 2, 2 \)) from Williamson Matrices
The most efficient ILP formulations for enumerating all OA($N, k, s, t$) extend all OA($N, i, s, t$) to all OA($N, i+1, s, t$) for $t \leq i \leq k-1$. Bulutoglu and Ryan [8] demonstrated a BILP formulation that extends a given OA($N, k-1, s, t$) to all possible OA($N, k, s, t$). Their BILP formulation is based on the following lemma in [8]

**Lemma 2.** Let $\mathbf{D}$ be a $N$-run, $k$-factor, $s$-level factorial design with columns $\{d_1, d_2, \ldots, d_k\}$. Let $\mathbf{D}'$ be the $N \times (s-1)k$ matrix with columns $\{d'_1, d'_2, \ldots, d'_{(s-1)k}\}$ where for $j = 1, 2, \ldots, k$ and $r = 1, 2, \ldots, s-1$ the $i$th entry of $d'_{(s-1)(j-1)+r}$ is 1 if the $i$th entry of $d_j$ is $r-1$ and is 0 otherwise. Then $\mathbf{D}$ is an OA($N, k, s, t$) if and only if

$$
\sum_{i=1}^{N} d'_{i_{h_1}}d'_{i_{h_2}} \cdots d'_{i_{h_q}} = \frac{N}{s^q} \quad \text{for } q = 1, 2, \ldots, t,
$$

(2.11)

and for all subset of size $q$ columns $\{d'_{h_1}, d'_{h_2}, \ldots, d'_{h_q}\}$ of $\mathbf{D}'$ such that $\left\lceil \frac{h_{i'}}{(s-1)} \right\rceil \neq \left\lceil \frac{h_{j'}}{(s-1)} \right\rceil$ for all $1 \leq i' < j' \leq (s-1)k$.

Let $\mathbf{D}'$ be a solution to the system of equations (2.11). Let the $j$th column of $\mathbf{D}$, $\mathbf{D}_j$ be

$$
\mathbf{D}_j = \sum_{r=1}^{s-1} (r-1)d'_{(s-1)(j-1)+r} + (s-1)\left(1_N - \sum_{r=1}^{s-1} d'_{(s-1)(j-1)+r}\right)
$$

for $j = 1, 2, \ldots, k$ [8]. Then, $\mathbf{D}$ is the corresponding OA($N, k, s, t$) obtained from $\mathbf{D}'$. For a known $N$-run, $(k-1)$-factor, $s$-level OA($N, k-1, s, t$) $\mathbf{D}$, Bulutoglu and Ryan [8] showed that all OA($N, k, s, t$) extensions of $\mathbf{D}$ can be constructed by utilizing a BILP via the algorithm described in Figure 2.3. All possible extensions of all OA($N, k-1, s, t$) to all OA($N, k, s, t$) are obtained by implementing the algorithm in Figure 2.3 with each OA($N, k-1, s, t$) $\mathbf{D}$ as input.
1. Follow Lemma 2 to construct $D'$ from input $D$.

2. Append to $D'$ $s - 1$ columns of binary variables $x_r = (x_{1r}, x_{2r}, ..., x_{Nr})^T$ for each $r = 1, 2, ..., s - 1$. (The system of equations (2.11) is linear with binary variables.)

3. For each pair of replicated run indices $1 \leq i'' < j'' \leq N$ in the input design and for any $q - 1$ columns $d'_{h_1}, d'_{h_2}, ..., d'_{h_{q-1}}$ as in Lemma 2 with the last $(s - 1)$ columns of $D$ deleted, find all feasible solutions to the BILP

$$\begin{align*}
\text{min} & \quad 0 \\
\text{s.t.} & \quad \sum_{i=1}^{N} x_{ir} = \frac{N}{s} \quad \text{for } r = 1, 2, ..., s - 1, \\
& \quad \sum_{i=1}^{N} d'_{h_1} d'_{h_2} \cdots d'_{h_{q-1}} x_{ir} = \frac{N}{sq} \quad \text{for } q = 2, ..., t \text{ and } r = 1, 2, ..., s - 1, \\
& \quad \sum_{r=1}^{s-1} x_{ir} \leq 1 \quad \text{for } i = 1, 2, ..., N, \\
& \quad \sum_{m=1}^{r} (x_{i'\prime m} - x_{j'\prime m}) \geq 0 \quad \text{for } r = 1, 2, ..., s - 1, \\
& \quad x_{i,1} = 1, \\
& \quad x_r \in \{0, 1\}^N \quad \text{for } r = 1, 2, ..., s - 1.
\end{align*}$$

(2.12)

4. Each solution matrix $[x_1, x_2, ..., x_{s-1}]$ to BILP (2.12) corresponds to an OA($N, k, s, t$) extension of the input OA($N, k-1, s, t$) and every extension corresponds to a solution matrix.

Figure 2.3: Identity Group Algorithm from Bulutoglu and Ryan [8]

Bulutoglu and Ryan [8] combined the ILP formulations in Figures 2.1 and 2.3 to create another formulation that extends all OA($N, k-1, s, t$) to all OA($N, k, s, t$) as in the above algorithm. This new formulation reduces the number of variables from $s^k$ in ILP (2.5) to $hs$, where $h$ is the number of distinct runs in the extended OA($N, k-1, s, t$). This additional extension formulation is described in Figure 2.4.
1. Follow Lemma 2 to construct $D'$ from input $D$. Let $r_i$ for $i = 1, 2, \cdots, s^{k-1}$ be the number of times the $i$th row of $D_{s}^{k-1}$ appears in the input design, where $D_{s}^{k-1}$ is all the $s^{k-1}$ level combinations with $k-1$ factors ordered lexicographically. Set $h$ equal to the number of distinct runs in $D$. Let $1 \leq i_1 \leq i_2 \leq \cdots \leq i_h \leq s^{k-1}$ be such that $r_{i_l} > 0$ for $l = 1, 2, \cdots, h$.

2. Define $1 = p_1 \leq p_2 \leq \cdots \leq p_h \leq N$ such that the $p_{l+1}$th row is the first row that differs from the $p_l$th row. Also, let $x$ be the indicator vector for the desired OA($N, k, s, t$) formatted as a solution to ILP (2.5) and $x^{h(s-1)}$ be $x$ with all of the entries that do not appear in the constraint matrix of ILP (2.13) deleted. This leaves the vector $x^{h(s-1)}$ with $h(s-1)$ entries.

3. For any $q-1$ columns $d'_{\alpha_1}, d'_{\alpha_2}, \ldots, d'_{\alpha_{q-1}}$ as in Lemma 2 with the last $(s-1)$ columns of $D'$ deleted, find all solutions to ILP (2.13).

4. Each solution $x^{h(s-1)}$ corresponds to an OA($N, k, s, t$) extension of the input OA($N, k-1, s, t$) and every such extension corresponds to a solution.

Figure 2.4: Extension to Improved Bulutoglu and Margot ILP [8]

Permuting the levels (symbols) of a factor in a factorial design is called a \textit{level permutation}. Two $k$-factor factorial designs are called \textit{isomorphic} if one can be obtained from the other by permuting its columns, rows, and applying level permutations in its
factors. For a given $s$-level, $k$-factor, $N$-run factorial design $D$, Bulutoglu and Ryan [8] defined a graph $G(D)$. They showed that $D_1$ and $D_2$ are isomorphic designs if and only if $G(D_1)$ and $G(D_2)$ are isomorphic graphs. The following steps extend the algorithm in Figure 2.4 to enumerate all non-isomorphic OA($N, k, s, t$) for $t + 1 \leq k \leq k_{\text{max}}(N, s, t)$, where $k_{\text{max}}(N, s, t)$ is the maximum number of factors such that an OA($N, k_{\text{max}}(N, s, t), s, t$) exists.

5. If there are no solutions, STOP.

6. Convert each OA($N, k, s, t$) from Step 4 to the graph defined by Bulutoglu and Ryan [8]. Let $\Omega$ be the set of resulting graphs.

7. Reduce $\Omega$ to a set of nonisomorphic graphs by using Nauty [25].

8. Retain only the OA($N, k, s, t$)'s that correspond to the retained graphs.

9. Set $k = k + 1$ and GO TO Step 1.

Figure 2.5: Additional Steps to Figure 2.4 to Enumerate Non-Isomorphic OA($N, k, s, t$) [8].

For $s = 2$, the following definitions and theorem were used by Bulutoglu [6] to extend the algorithm in Figure 2.4 to find the maximum number of factors, $k_{\text{max}}$ such that an OA($N, k_{\text{max}}, 2, t$) exists.

**Definition 1.** Let $Y_1$ and $Y_2$ be 2-level, $k$-factor factorial designs whose levels are $\pm 1$. Then, $Y_1$ and $Y_2$ are called Hadamard equivalent if $Y_2$ can be obtained from $Y_1$ by applying signed permutations to the columns and/or rows of $Y_1$ [24].

**Definition 2.** Let $X_1$ and $X_2$ be 2-level, $k$-factor factorial designs whose levels are $\pm 1$. Then, $X_1$ and $X_2$ are called Orthogonal Design (OD) equivalent if $[1 \ X_2]$ is Hadamard equivalent to $[1 \ X_1]$ [6].

Bulutoglu [6] showed the following result:
Theorem 2. Let \( k_1 < k_2 \) and \( \mathbf{X}_1 \) be an \( OA(N, k_1, 2, t) \) that extends to an \( OA(N, k_2, 2, t) \). If \( \mathbf{X}_2 \) is an \( OA(N, k_1, 2, t) \) that is OD equivalent to \( \mathbf{X}_1 \), then \( \mathbf{X}_2 \) also extends to an \( OA(N, k_2, 2, t) \).

For a 2-level, \( k \)-factor, \( N \)-run design \( \mathbf{Y}_1 \), McKay [24] defined a graph \( X(\mathbf{Y}_1) \) with 2 \((k + N)\) vertices and showed that \( \mathbf{Y}_1 \) is Hadamard equivalent to \( \mathbf{Y}_2 \) if and only if \( X(\mathbf{Y}_1) \) and \( X(\mathbf{Y}_2) \) are isomorphic graphs.

For \( s = 2 \), the algorithm in Figure 2.5 is modified to find a set of all non-OD equivalent \( OA(N, k, 2, t) \) for \( k \leq k_{\text{max}}(N, 2, t) \) by replacing Step 6 with the following step:

6. Add a column of 1’s to each \( OA(N, k, 2, t) \) from Step 4. Convert each resulting design to the graph defined by McKay [24]. Let \( \Omega \) be the set of resulting graphs.

Figure 2.6: New Step 6 in Figure 2.5 Algorithm to Find \( k_{\text{max}}(N, 2, t) \) [6].

The modified Figure 2.5 algorithm is faster as it requires solving much fewer ILPs at each extension step. Also, a set of all non-isomorphic \( OA(N, k, 2, t) \) can be extracted from a set of non-OD equivalent \( OA(N, k, 2, t) \). Hence, the modified Figure 2.5 algorithm can be used to enumerate all non-isomorphic \( OA(N, k, 2, t) \) for \( k \leq k_{\text{max}}(N, 2, t) \).

These are just a few different ways that ILPs are used to enumerate OAs. The next section defines the symmetry group of an ILP.

### 2.3 Symmetry Groups in ILPs

In order to study the symmetries of an ILP, some definitions are introduced. \( I^n = \{i \in \mathbb{Z}_{\geq 0} \mid i \leq n\} \) is the ground set of size \( n \). Let \( S_n \) be the set of all permutations of the elements in \( I^n \). Let \( \pi_i \) be the image of \( i \in I^n \) under the permutation \( \pi \). The identity permutation \( I \) is such that \( \pi_i = i \quad \forall \ i \in I^n \). For any \( \mathbf{v} \in \mathbb{R}^n \), let \( \mathbf{w} = \pi(\mathbf{v}) \) indicate the vector \( \mathbf{w} \in \mathbb{R}^n \) that results from applying the permutation \( \pi \) to \( \mathbf{v} \). For any two permutations \( \pi^1, \pi^2 \in S_n \), the composition of these two permutations is \( \pi^1(\pi^2) \). The common notation
for this is $π^1 \cdot π^2$. The identity for the composition of permutations is the aforementioned identity permutation $I$, where $π \cdot I = I \cdot π = π \ \forall \ π \in S_n$. For any $π^1, π^2, π^3 \in S_n$, $$(π^1 \cdot π^2) \cdot π^3 = π^1 \cdot (π^2 \cdot π^3) \ \text{i.e.} \ \text{the composition of permutations is associative} \ [23].$$

The subset $G \subseteq S_n$ is called a group if it has the following properties:

1. $I \in G$.

2. $π^1 \cdot π^2 \in G \ \forall \ π^1, π^2 \in G$.

3. For all $π \in G$, there exists a unique inverse $π^{-1} \in G$ such that $π \cdot π^{-1} = π^{-1} \cdot π = I$.

The number of permutations in $G$ is called the order of the group, denoted by $|G|$. For example, $|S_n| = n!$. A subgroup is a subset of $G$ that is also itself a group. All groups in this dissertation have finite order, as their elements are permutations of finite sets [23].

Margot [23] defined the symmetry group $G$ of an ILP as $$G = \{π \in S_n \mid c^T x = c^T π(x) \ \text{and} \ π(x) \in \mathcal{F} \ \forall \ x \in \mathcal{F}\},$$
where $\mathcal{F}$ is the set of all feasible solutions to the ILP. Elements of a set $Ω \subseteq S_n$ which can be composed in some way some number of times to obtain each permutation in the group $G \subseteq S_n$, are called generators of the group $G$, and $G$ is said to be generated by $Ω$. A set of $O(n^2)$ generators is all that is needed to generate any subgroup of $S_n$ [23]. Additionally, the stabilizer of a vector $v ∈ \mathbb{R}^n$ under $G$ is $$\text{stab}(v, G) = \{π \in G \mid v = π(v)\}$$ and the orbit of a vector $v ∈ \mathbb{R}^n$ under $G$ is $$\text{orb}(v, G) = \{w ∈ \mathbb{R}^n \mid w = π(v) \ \text{for at least one} \ π \in G \subseteq S_n\}.$$ The restriction of $G$ to $J$ is the set of all permutations of just the elements of a nonempty set $J \subseteq \{1, 2, ..., n\}$ that are induced by the permutations in $\text{stab}(J, G)$. The restriction is itself a group. Finally, $v ∈ \mathbb{R}^n$ is lexicographically smaller (larger) than $w ∈ \mathbb{R}^n$ if $v_j = w_j$ and $v_k < w_k \ (v_k > w_k)$ for some $k$ with $1 ≤ j < k$ and $1 ≤ k ≤ n$. The notation for this is $v <_L w \ (v >_L w)$ [23].
The definitions provided in this section provide a framework for the discussions in the next section. Next section discusses how symmetry groups in OA-generating ILPs relate to isomorphism of OAs.

2.4 Symmetry in ILPs and Isomorphism of OAs

As previously discussed, OAs are known to be universally optimal for estimating certain statistical models [35]. It is well known that isomorphic designs have the same GWP. Thus, the GMA property is invariant between isomorphic designs. It is often quite difficult to determine whether an OA($N, k, s, t$) exists for a given $N, k, s, t$ combination. However, if one OA($N, k, s, t$) is found, it is just a matter of permuting symbols, rows and/or columns to find other OAs that are isomorphic to this OA.

Additionally, since the ILPs of interest are constructed to generate OAs that are isomorphic to many other OAs, these ILPs all contain variables that can be permuted without changing the problem. Any ILP that contains at least some variables that can be permuted without changing the feasibility and optimality of its solutions is said to be symmetric. Many classical problems in operations research, combinatorics and statistical experimental design are formulated as symmetric ILPs. In addition to generating orthogonal arrays, symmetric ILPs are frequently encountered in job scheduling, code construction, covering design construction and graph coloring problems [23].

There are a number of commercial and academic solvers available that are designed to find all optimal solutions to ILPs. The Branch-and-Bound and Branch-and-Cut algorithms are commonly used. Several researchers have been successful in using variations of these algorithms to generate OAs from symmetric ILPs (see [2], [3], [8], and [7]).

For symmetric ILPs, many of the subproblems in the ILP enumeration tree are isomorphic, meaning that a substantial amount of computational effort is wasted on solving subproblems that are identical to each other [23]. Hence for symmetric ILPs with large symmetry groups, it can be very difficult to find optimal solutions or prove infeasibility
using the classical algorithms. Margot [22] developed a solver that eliminates evaluation of isomorphic subproblems in the ILP enumeration tree, thereby greatly speeding up the enumeration of the ILP solutions. The Margot ILP solver [22] exploits the symmetry group of an ILP in pruning its enumeration tree.

Bulutoglu and Margot [7] defined the isomorphism group $G_{s,k}$ of a $k$ factor, $s$-level design $D$ to be the group of all permutations of factors as well as permutations of levels within each factor in $D$. The definition of $G_{s,k}$ does not mention runs. This is because run order is irrelevant when a factorial design is viewed as a set of frequencies for the set of distinct runs possible in the design [7]. There exists an element $g \in G_{s,k}$ such that $g(x_1) = x_2$ if and only if $x_1$ and $x_2$ are the indicator vectors of isomorphic designs $D_1$ and $D_2$. Note that $|G_{s,k}| = k!(s!)^k$ and $G_{s,k} \cong S_s \wr S_k$, where $\wr$ is the wreath product. Bulutoglu and Margot [7] showed that the Branch-and-Cut with isomorphism pruning algorithm in Margot [22] returns exactly one OA($N, k, s, t$) for each isomorphism class if it uses the group $G_{s,k}$ [7].

The automorphism group of an ILP of the form

$$
\begin{align*}
\text{min} & \quad e^T x \\
\text{s.t.} & \quad Ax = b, \\
& \quad d \geq x \geq 0, \quad d_i, x_i \in \mathbb{Z}_{\geq 0},
\end{align*}
$$

is defined as

$$
G(A, b, c, d) = \{\pi \in S_n \mid \pi(c) = c, \pi(d) = d \text{ and } \exists \sigma \in S_m : A(\pi, \sigma) = A \text{ and } \sigma(b) = b\},
$$

where $A(\pi, \sigma)$ is the matrix obtained by permuting the rows of $A$ according to $\sigma$ and columns according to $\pi$. Bulutoglu and Margot [7] proved the following theorem:

**Theorem 3.** For ILP (2.4), let $G(A, \lambda 1, 1, p_{\max} \lambda 1)$ be the automorphism group of the ILP, $G_{s,k}$ be the isomorphism group of an OA($N, k, s, t$) and $S_{s^k}$ be the set of all possible permutations of $\{1, 2, \ldots, s^k\}$. Then, $G_{s,k} \leq G(A, \lambda 1, 1, p_{\max} \lambda 1)$ for $0 < t < k$ and $G_{s,k} \subset G(A, \lambda 1, 1, p_{\max} \lambda 1) = S_{s^k}$ otherwise.
Margot [23] declares two solutions to ILP (2.14) to be isomorphic if one can be obtained from the other by applying a permutation belonging to the automorphism group $G(\mathbf{A}, \mathbf{b}, \mathbf{c}, \mathbf{d})$. Bulutoglu and Margot [7] used the isomorphism pruning integer programming solver developed by Margot [22] to enumerate all non-isomorphic orthogonal arrays for many $N, k, s, t$ combinations. Their enumeration was based on finding all non-isomorphic solutions to ILP (2.4) using the group $G(\mathbf{A}, \lambda \mathbf{1}, \mathbf{1}, \mathbf{p}_{\text{max}} \mathbf{1})$. This was allowed, as in all the cases they considered, $|G_{s,k}| = |G(\mathbf{A}, \lambda \mathbf{1}, \mathbf{1}, \mathbf{p}_{\text{max}} \mathbf{1})|$. The results obtained by Bulutoglu and Margot [7] based on Theorem 3 indicate that there are major efficiencies to be gained by using the isomorphism pruning method in Margot [22] to solve ILPs of the form in ILPs (2.4) and (2.13). However, in order for the Margot ILP solver [22] to be more effective, an efficient methodology for identifying all symmetries in ILPs is required.

2.5 Identifying Symmetries in ILPs

Clearly, the automorphism group of an ILP of the form (2.14) is a subgroup of its symmetry group. However, there is no guarantee that all symmetries of such an ILP will be captured by its automorphism group. In fact, it is easy to construct examples of ILPs with equality constraints only in which the symmetry group is much larger than the automorphism group. On the other hand, identifying the full symmetry group $G$ for an ILP formulation is a difficult open problem.

Therefore, it is worthwhile to develop techniques to find a set of generators of the symmetry group for any ILP. The most difficult obstacle to overcome when developing such a technique is that the makeup of $G$ is inherently determined by the ILP’s feasible set [23]. For example, the definition of a symmetry group says that $G = S_n$ for an infeasible ILP with $n$ variables. Margot [23] proved that deciding if $G = S_n$ is an $NP$-Complete problem. Hence, finding the symmetry group $G$ of an ILP is $NP$-Hard. Assuming $P \neq NP$, there is no way to find a polynomial-time algorithm for finding generators of $G$. One approach that
is often effective is to find the symmetry group of the LP relaxation of the ILP. Margot \[23\] defined this group as the set of all permutations of the LP that send feasible points to feasible points with the same objective function value. $G^{LP}$ is the set of all permutations that send facets of the LP relaxation to facets and fixes the objective function provided that the LP relaxation is full dimensional. Then for an ILP in the form

$$\begin{align*}
\text{min} & \quad c^T x, \\
\text{s.t.} & \quad Ax \geq b, \\
& \quad x \in \mathbb{Z}_{\geq 0},
\end{align*}$$

(2.16)

$G(A, b, c) = G^{LP}$ provided that the LP relaxation of the ILP has no redundant constraints and contains interior points (i.e. it is full dimensional). On the other hand, for an ILP of the form (2.14), all we can say is $G(A, b, c) \leq G^{LP}$. In Chapter 4, methods are developed to find $G^{LP}$ for ILPs with equality constraints only. $G^{LP}$s of LPs with equality constraints have not yet been studied in the literature. $\mathcal{F}(k, s, t) \subseteq \mathcal{F}(k, s, t)^{LP}$ implies $G^{LP} \leq G$ as non-integer solutions in $\mathcal{F}(k, s, t)^{LP}$ can break symmetries that would otherwise be present in $G$ \[23\]. It is possible that working with $G^{LP}$ may be less efficient, but for most ILP formulations of OAs are such that $G^{LP}$ is either a large subgroup of $G$ or it is equal to $G$ itself.

Now, consider the matrix

$$L = \begin{bmatrix} 0 & A^T \\ A & 0 \end{bmatrix}$$

where $A$ is the $(0, 1)$ ILP (2.16) constraint matrix. The matrix $L$ can be seen as the adjacency matrix of a bipartite graph $K$ with colored vertices. $K$ has one vertex for each row and one vertex for each column of $A$. The set of vertices for the rows constitute one side of the bipartition and the vertices for the columns constitute the other. Two column (row) vertices in $K$ have the same color if and only if their corresponding objective function (right hand side) coefficients are equal. Margot \[23\] showed that the automorphism group of $K$ is equal to $G(A, b, c)$. (The automorphism group of a vertex colored graph is the set of
all permutations of its vertices that send adjacent vertices to adjacent vertices and preserve colors.)

In cases where the ILP constraint matrix $A$ is not $(0, 1)$, there are many mappings of the ILP to an edge colored vertex colored graph such that the color preserving automorphisms of the graph correspond to the symmetries of the ILP. One example in the literature is in [30]. In this work, the code created by Bulutoglu and Ryan [8] is used for this purpose. The problem of determining the automorphism group of a graph is at least as computationally complex as the famous Graph Isomorphism problem [23]. However, there are software packages available such as Nauty [25] and GAP [12] that can solve this problem in most instances.

### 2.6 Margot ILP Solver [22]

The Margot ILP solver [22] utilizes a modified version of the Branch-and-Cut algorithm for solving ILPs. The modification is in the pruning step. Instead of pruning just one subproblem, the Margot ILP solver [22] prunes the entire set of isomorphic subproblems. For ILPs whose symmetry groups are large, this modification greatly increases the efficiency of the Branch-and-Cut if one is able to exploit a large subgroup of the symmetry group.

Margot developed his modified Branch-and-Cut algorithm over a series of papers [19], [20], [21] and [22]. The reader is referred to [21] for the most basic version of his Branch-and-Cut algorithm for binary ILPs. In [19], he made his algorithm more efficient by introducing zero setting. In [20], he incorporated strict zero setting and ranked branching. In [22], he generalized his algorithm in [20] to bounded ILPs where each variable is bounded by a constant.

The next chapter discusses theoretical work that lead to the research objectives and results listed in Chapter 4.
III. Theoretical Research

3.1 Chapter Introduction

This chapter discusses the theoretical research efforts based on the review of current literature provided in Chapter 2. In Section 3.2, Lemma 1 is used to define the linear relaxation orthogonal array polytope of an OA(λs', k, s, t). An OA(λs', k, s, t) exists if and only if its linear relaxation orthogonal array polytope contains integer vectors where each integer vector represents an OA(λs', k, s, t). In this section, it is shown that the stated formulation defining the linear relaxation orthogonal array polytope does not contain redundant inequalities. This implies that each inequality is a facet. In Section 3.3, a large subgroup of all the permutation symmetries of the linear relaxation orthogonal array polytope of OA(λs', k, s, t) is found. It is shown that the subgroup found is equal to the group of all the permutation symmetries. This result is computationally verified for many cases.

3.2 The Linear Relaxation OA Polytope

The following theorem follows immediately from Lemma 1 in Section 3.2 by taking \( z = 1 \) and observing that \( N_x \geq 0 \).

**Theorem 4.** Let \( \{a_c\} \) and \( I_x \) be as in Lemma 1. Let \( 0 \leq d(1, x) \leq t \) and

\[
a_{t-d(1,x)} + (-1)^{t-d(1,x)} + \sum_{y \in J_x} \left( d(1, y) - d(1, x) - 1 \right) N_y \geq 0,
\]

\[
N_y \geq 0,
\]

where \( J_x = \{ y \in \{1, \ldots, s\}^k : y_i = x_i \ \forall i \in I_x \} \). Then an OA(\( \lambda s', k, s, t \)) exists if and only if there exist integers \( N_y \) satisfying the inequalities (3.1).

Theorem 4 converts the Bulutoglu and Margot [7] ILP with equalities to an ILP problem with inequalities only. This is done by deleting the set of basic variables \( N_x \) with
after implementing Gaussian elimination. Deletion of these variables is only possible because the coefficients of all $N_x$ are 1 and the coefficients of $N_y$ with $d(y, 1) > t$ are all integers at the end of Gaussian elimination. The substance of Lemma 1 from [29] is that it correctly identifies which set of basic variables has elements that are all integer combinations of the remaining variables. This enables the deletion of this set of variables from the Bulutoglu and Margot [7] ILP. The new ILP has the form

$$\begin{align*}
\text{min} & \quad 0 \\
\text{s.t.} & \quad A'(k, s, t)x' \geq b_m \\
& \quad x \in \{0, 1, 2, \ldots, p_{\max}\}^{x - m}, \tag{3.2}
\end{align*}$$

where $m = \sum_{i=0}^{t} \binom{k}{i} (s - 1)^i$, and $A'(k, s, t)$, $b_m$, $x'$ are the results of applying Gaussian elimination to $[A(k, s, t) \mid \lambda I^{(t)}]$, and deleting the basic variables $N_x$.

For a general ILP with only equality constraints over non-negative integer vectors, deleting variables by using Gaussian elimination may not always be possible. This can be the case for one of two reasons. First, there may be no set of basic variables whose elements are integer combinations of the remaining variables plus some integer. Second, it may be very difficult to identify such a set of basic variables. For example, for the ILP in [7] when $k = 8$, $s = 2$ and $t = 3$, the proportion of such sets of of basic variables to all sets of basic variables was estimated to be 0.5%. This estimate was calculated by repeating the following procedure 1000 times.

1. Randomly permute the columns of the constraint matrix.

2. Augment the resulting matrix with its right hand side.

3. Row reduce it to its reduced row echelon form.

4. Record if the output has only integer entries.

The MATLAB code to execute this procedure is given in Section A.2.
The following definition arises naturally from Theorem 4.

**Definition 3.** Let \( m = \sum_{i=(t+1)}^k \binom{k}{i} (s - 1)^i \). The set of \( \mathbf{N} \in \mathbb{R}^m \) with \( k \geq d(\mathbf{1}, \mathbf{y}) \geq t + 1 \) that satisfy the system of inequalities (3.1) is called the linear relaxation polytope of \( \text{OA}(\lambda s^t, k, s, t) \).

Let \( \text{OAP}(k, s, t, \lambda) \) denote the linear relaxation polytope of \( \text{OA}(\lambda s^t, k, s, t) \). Note that \( \text{OAP}(k, s, t, \lambda) \) is a polytope not an unbounded polyhedron because it can be embedded inside the hypercube \([0, \lambda]^m\).

**Theorem 5.** The \( \text{OAP}(k, s, t, \lambda) \) is full dimensional for all \( \lambda \).

**Proof.** Let \( m \) be as above and \( \mathbf{1}_m \) be the \( m \times 1 \) vector of all 1s. This result is proven by showing that \( \lambda/s^{k-t} \mathbf{1}_m \) is an interior point of the \( \text{OAP}(k, s, t, \lambda) \). Rosenberg [29] showed that the system of equations in Lemma 1 is equivalent to

\[
\sum_{\mathbf{x} \in [s]^k, x_i \in I} N_x = \lambda \quad \text{for all } I \text{-subsets of } [k] \text{ and all } \mathbf{a} \in [s]^k
\]

where \([s]^k = \{1, 2, \cdots, s\}^k \) and \([k] = \{1, 2, \cdots, k\} \). It is clear that \( \lambda/s^{k-t} \mathbf{1}_m \) solves the system of equations (3.3) in \( \mathbb{R}_{\geq 0}^k \). Then \( N_x = \lambda/s^{k-t} \) and \( N_y = \lambda/s^{k-t} \) for \( d(\mathbf{x}, \mathbf{1}) \leq t \) and \( d(\mathbf{y}, \mathbf{1}) > t \) respectively solves the system of equations (2.2) Lemma 1 in \( \mathbb{R}_{\geq 0}^k \). Now, clearly \( \lambda/s^{k-t} \mathbf{1}_m \) satisfies all the inequalities defining the \( \text{OAP}(k, s, t, \lambda) \) strictly. Hence, it is an interior point. \( \square \)

The following theorem proves that no constraint in Theorem 4 is redundant unless \( k = t + 1 \) and \( s = 2 \).

**Theorem 6.** Each one of the distinct \( s^k \) inequalities in Theorem 4 defining the \( \text{OAP}(k, s, t, \lambda) \) is a facet and no facet is repeated unless \( k = t + 1 \) and \( s = 2 \).

**Proof.** At least one of the inequalities in (3.1) is a facet since otherwise \( \text{OAP}(k, s, t, \lambda) \) would be an unbounded polyhedron. Then there exists \( \mathbf{N} \in \mathbb{R}^m \) satisfying all but the
facet defining inequality in (3.1). Let \( N^f_{u_0} < 0 \), \( N^f_{u_0} \in \mathbb{R} \) be the left hand side in constraints (2.2) corresponding to the facet defining inequality in (3.1), where

\[
f(u) = \begin{cases} 
  x & \text{if } d(u, 1) \leq t, \\
  y & \text{otherwise.}
\end{cases}
\]

Hence, there exists vectors \( N^y \in \mathbb{R}^m \) and \( N^x \in \mathbb{R}^{s-k} \) that satisfy the equations in constraints (2.2) such that \( N^y \geq 0 \) and \( N^x \geq 0 \) for \( x \neq u_0 \) and \( y \neq u_0 \), where \( N^f_{u_0} < 0 \). The group \( G_{s,k} \cong S_s \wr S_k \) sends vectors in \( \mathbb{R}^s \) that satisfy the equations in constraints (2.2) to vectors that satisfy the same equations. Furthermore \( G_{s,k} \) acts transitively on the variables of constraints (2.2). Hence, for each \( u_0 \in [s]^k \), there exists a solution with \( N^f_{u_0} < 0 \) and \( N^f_{w} \geq 0 \) for \( w \neq u_0, w \in [s]^k \). Then there exists \( N^y \in \mathbb{R}^m \) satisfying all but one facet defining inequality in (3.1) whose left hand side is \( N^f_{u_0} < 0 \) in constraints (2.2) for arbitrary \( u_0 \in [s]^k \). Hence, there are no distinct redundant inequalities in (3.1) and each distinct inequality is a facet.

Observe that unless \( k = t + 1 \) and \( s = 2 \), \( \{ y \in J_{x_1} : d(1, y) > t \} \neq \{ y \in J_{x_2} : d(1, y) > t \} \) whenever \( x_1 \neq x_2 \). Hence, no facet is repeated unless \( k = t + 1 \) and \( s = 2 \). For the degenerate case \( k = t + 1 \) and \( s = 2 \), there is only one variable \( N^y_{(2,2,\ldots,2)} \) and one gets \( N^y_{(2,2,\ldots,2)} \geq 0 \) and \( -N^y_{(2,2,\ldots,2)} \geq -\lambda \) each repeated \( 2^{k-1} \) times. \( \square \)

**Remark 1.** While it is true that \( S_s \wr S_k \) acts as a group of symmetries on \( \text{OAP}(k, s, t, \lambda) \), this action is no longer as a group of linear transformations (as is the case for the full system of equations (3.3)), but rather as a group of affine transformations. In particular \( S_s \wr S_k \) does not permute the variables of \( \text{OAP}(k, s, t, \lambda) \), but rather, it acts by permuting the half-spaces defined by inequalities (3.1). Furthermore, this action is transitive.

Theorem 6 was verified when \( \lambda = 1 \) for each of \( s = 2, 4 \leq k \leq 13, 2 \leq t \leq k - 2, s = 3, 3 \leq k \leq 8, 2 \leq t \leq k - 1 \) and \( s = 4, 3 \leq k \leq 6, 2 \leq t \leq k - 1 \) cases. This verification was based on finding interior points on each facet of the \( \text{OAP}(k, s, t, \lambda) \).
Let $B \mathbf{x} \leq d$ be the system of inequalities in Theorem 4 defining the OAP($k, s, t, \lambda$). Let $B' \mathbf{x} \leq d'$ be the same system after the $i^{th}$ inequality is deleted. Also, let $(\mathbf{b}_i)^T$ be the $i^{th}$ row of $B$ and $F_i$ be the hyperplane defined by the equality $(\mathbf{b}_i)^T \mathbf{x} = d_i$. To find interior points on $F_i \cap \text{OAP}(k, s, t, \lambda)$, each face of the OAP($k, s, t, \lambda$), feasible solutions were found to the following linear program

$$\min \quad \mathbf{1}^T \mathbf{x}$$
$$\text{such that} \quad (\mathbf{b}_i)^T \mathbf{x} = d_i$$
$$B' \mathbf{x} \leq d' - \frac{1}{1000} \mathbf{1}.$$

The MATLAB code to implement this test is found in Section A.4.

### 3.3 Permutation Symmetries of the OA Polytope

First, a definition for the permutation symmetries of a polytope:

**Definition 4.** Let $P$ be a full dimensional polytope in $\mathbb{R}^m$. A permutation of coordinates of $\mathbb{R}^m$ that also sends $P$ onto itself is called a permutation symmetry of $P$. The set of all such transformations forms a group called the permutation symmetry group ($\Pi(P)$) of $P$.

The variables $N_y$ in Theorem 4 are indexed by all factor level combinations $y \in [s]^k$ with $d(y, 1) > t$ and $\Pi(\text{OAP}(k, s, t, \lambda))$ permutes those variables. The following theorem explicitly describes a nontrivial subgroup of $\Pi(\text{OAP}(k, s, t, \lambda))$.

**Theorem 7.** Let

$$H_{k,s,t} = \begin{cases} 
S_{s^k-1} & \text{if } t = 0, \\
S_{(s-1)^k} \wr S_k & \text{if } 0 < t < k \text{ and } (k > t + 1 \text{ or } s > 2), \\
I & \text{otherwise},
\end{cases}$$

and $I$ be the identity group. Also, let $Y = \{ y \in [s]^k : d(y, 1) > t \}$. Then, when $H_{k,s,t}$ is not defined to be $I$, it naturally embeds as the group of permutations that preserve $Y$, and $H_{k,s,t} \subseteq \Pi(\text{OAP}(k, s, t, \lambda))$. 

30
Proof. It is easy to see that each element of $H_{k,s,t}$ maps Definition 3 defining constraints of the OAP($k, s, t, \lambda$) to each other. Then, $\mathbf{v} \in \text{OAP}(k, s, t, \lambda) \Rightarrow h(\mathbf{v}) \in \text{OAP}(k, s, t, \lambda)$ for all $h \in H_{k,s,t}$. Hence, $H_{k,s,t}$ maps the OAP($k, s, t, \lambda$) into itself. On the other hand, for a given $\mathbf{v} \in \text{OAP}(k, s, t, \lambda)$, one has $h(h^{-1}(\mathbf{v})) = \mathbf{v}$ as $h^{-1}(\mathbf{v}) \in \text{OAP}(k, s, t, \lambda)$. This implies that $h(\text{OAP}(k, s, t, \lambda)) = \text{OAP}(k, s, t, \lambda)$ for each $h$. Hence, $H_{k,s,t} \subseteq \Pi(\text{OAP}(k, s, t, \lambda))$. The second part of the theorem follows directly from the definition of wreath product of groups. □

Remark 2. For $k = t + 1$ and $s = 2$ there is only one variable $N_y$ with $d(y, 1) > t$, hence $\Pi(\text{OAP}(k, s, t, \lambda)) = \{1\}$. For the case $t = 0$, there is one constraint on the $s^k - 1$ variables. The coefficients of this constraint are all $-1$s, hence $H_{k,s,0} \cong S_{s^k-1}$. If $t = k$ there are no variables in inequalities (3.1).

Next, tools are developed for computing $\Pi(\text{OAP}(k, s, t, \lambda))$. As noted in [23], the set of all permutations of coordinates in $\mathbb{R}^m$ mapping $P$ onto itself consists of all permutations of coordinates that map facets of $P$ onto its facets. Hence, if all the facets of an OAP($k, s, t, \lambda$) are known, then $\Pi(\text{OAP}(k, s, t, \lambda))$ can be computed explicitly. $\Pi(\text{OAP}(k, s, t, \lambda))$ were computed explicitly for all the $k, s, t$ combinations in which Theorem 6 was verified. This was done by first finding

$$G_{k,s,t} = \{ \pi \mid \exists \sigma : A_{k,s,t}(\pi, \sigma) = A_{k,s,t} \}$$

where $A_{k,s,t}$ is the constraint matrix of inequalities (3.1) in Theorem 4 and $A_{k,s,t}(\pi, \sigma)$ is the resulting matrix when the rows of $A_{k,s,t}$ are permuted according to $\sigma$ and columns according to $\pi$. Then, $H_{k,s,t} \leq \Pi(\text{OAP}(k, s, t, \lambda)) \leq G_{k,s,t}$ as $\Pi(\text{OAP}(k, s, t, \lambda))$ must preserve the constraint matrix. Calculating $G_{k,s,t}$ over directly calculating $\Pi(\text{OAP}(k, s, t, \lambda))$ was done for the sake of convenience. Finding only $G_{k,s,t}$ proved to be sufficient in all the cases.
considered. $G_{k,s,t}$ was calculated as described in [23], by first mapping the matrix

$$
\begin{bmatrix}
0 & A_{k,s,t} \\
A_{k,s,t}^T & 0
\end{bmatrix}
$$

to an edge colored graph and then finding the automorphism group. The code to generate the constraints (3.1) is found in Section A.3. The code used to generate $G_{k,s,t}$ for various values of $k$, $s$ and $t$ can be found in Section A.4. Nauty software [25] was used to find the automorphism groups. In all the $k,s,t$ cases studied, it was found that $|G_{k,s,t}| = ((s - 1)!)^k k! = |H_{k,s,t}|$ implying $H_{k,s,t} = \Pi(\text{OAP}(k,s,t,\lambda))$. To prove this observation, the following two lemmas are required.

**Lemma 3.** Let $GG$ be the group of maps $\phi$ from $[s]^k$ to $[s]^k$ that preserve the Hamming distance, i.e. $d(x,y) = d(\phi(x), \phi(y))$ for all $\phi \in GG$ then $GG \cong S_s \wr S_k$. Furthermore, if $G_1$ is the subgroup of $GG$ such that $\tau(1) = 1$ for all $\tau$ in $G_1$ then $G_1 \cong S_{(s-1)} \wr S_k$.

**Proof.** Replace $\mathbb{F}_q$ with $\mathbb{Z}_s$, the ring of integers mod $s$ and $\mathbb{F}_q^*$ with $\mathbb{Z}_s - \{0\}$ in Theorem 5 and Theorem 6 as well as in their proofs in [11]. Also, replace the term “vector space” with “$\mathbb{Z}_n^*$”. Then the resulting theorems and their proofs are still valid as the proofs never use the multiplicative invertibility of non-zero elements. Now, replace $\{0, 1, \cdots, s-1\}$ with $\{1, \cdots, s\}$ to get

$$GG = S_{\{1,\cdots,s\}} \wr S_k \cong S_s \wr S_k$$

and

$$G_1 = S_{\{2,\cdots,s\}} \wr S_k \cong S_{(s-1)} \wr S_k.$$ 

□

**Lemma 4.** If $k-t \geq 2$ then $\{a_{c,t}\}_{c=0}^t$ in Theorem 4 are all non-zero and distinct.

**Proof.** $\{a_{c,t}\}_{c=0}^t$ in Lemma 1 are the same $\{a_{c,t}\}_{c=0}^t$ in Theorem 4. $N_x = \lambda/s^{k-t}$ and $N_y = \lambda/s^{k-t}$ solves the Lemma 1 system of constraints. Plugging in $N_x = \lambda/s^{k-t}$, $N_y = \lambda/s^{k-t}$ and

32
multiplying both sides of equations (2.2) by $s^{k-t}/\lambda$ leads to

$$
\frac{s^{k-t}}{\lambda} a_t = 1 + (-1)^{t-r} \left( \sum_{i=1}^{k-t} \frac{t-i-r}{t-i} \right).
$$

(3.4)

Taking $z = 1$ and $x = (2(1), (1)_{k-r})^T$ equation (3.4) implies that

$$
\frac{s^{k-t}}{\lambda} a_t = 1 + (-1)^{t-r} \sum_{i=1}^{k-t} (s-1)^{(t-r)+i} \left( \frac{k-r}{t-i} \right).
$$

(3.5)

There are $k-t \geq 2$ positive integers inside the summation in equation (3.5). This implies that $a_c \neq 0$ for $0 \leq c \leq t$ and $a_c^r a_{c+1} < 0 \Rightarrow a_c \neq a_{c+1}$ for $0 \leq c \leq t-1$. Furthermore, if $a_t = a_{t-r_1}$ for some $1 \leq r_2 < r_1 \leq t$, then one must have $r_1 \equiv r_2 \pmod{2}$. This further implies that

$$
\sum_{i=1}^{k-t} (s-1)^{(t-r_1)} \left( \frac{k-r_1}{t-i-r_1} \right) = \sum_{i=1}^{k-t} (s-1)^{(t-r_2)} \left( \frac{k-r_2}{t-i-r_2} \right).
$$

for some $0 \leq r_2 < r_1 \leq t$. However, this is impossible as

$$
0 < (s-1)^{(t-r_1)} \left( \frac{k-r_1}{t-i-r_1} \right) \leq \sum_{i=1}^{k-t} (s-1)^{(t-r_2)} \left( \frac{k-r_2}{t-i-r_2} \right).
$$

Hence, $a_t \neq a_{t-r_1}$ and $|a_t| < |a_{t-r_1}|$ for all $1 \leq r_2 < r_1 \leq t$. Finally, each $a_c$ is divisible by $\lambda = a_0$ by the nature of the difference equation defining $a_c$ and $|a_c|$ is strictly increasing with $c$ as $c$ goes from 1 to $t$. Hence, $a_c \neq a_0 = \lambda$ for $c \neq 0$. \hfill \Box

Equation (3.5) provides a closed form formula for the solution of the inhomogeneous recurrence relation of degree $k-t+1$ in Lemma 1. This recurrence relation is equivalent to a homogeneous recurrence relation of degree $k-t+2$. Solving such an equation requires finding all complex roots of a degree $k-t+2$ polynomial. Coming up with this closed form formula for arbitrary values of $k-t$ without relating $a_c$ to the orthogonal array problem appears to be difficult.

**Theorem 8.** $\Pi(OAP(k, s, t, \lambda)) = H_{k, s, t}$. 

33
Proof. By Remark 2 it suffices to consider the case \(1 \leq t \leq k - 1\) and \((k > t + 1\) or \(s > 2\). For \(z = 1\), let \(GR\) be the group of all coordinate permutations of \([s]^k\) which permute the facets in Theorem 4. Then,

\[
y \in J_x \Leftrightarrow \sigma(y) \in J_{\sigma(x)} \quad (3.6)
\]

and \(a_{t-d(1,x)} = a_{t-d(\sigma(1),\sigma(x))}\) for all \(x\) such that \(0 \leq d(1,x) \leq t\) and all \(\sigma \in GR\). The distinctness of \(\{a_c\}_{c=0}^t\) further implies that

\[
d(1,x) = d(\sigma(1), \sigma(x)) \quad \text{if} \quad d(1,x) \leq t.
\]

Since

\[
a_{t-d(1,1)} + (-1)^{t-d(1,1)+1} \sum_{y \in J_1, d(1,y) = t} \left( \frac{d(1,y) - d(1,1) - 1}{t - d(1,1)} \right) N_y \geq 0,
\]

when \(x = 1\), is the only inequality in inequalities (3.1) that has \(a_t\) as its constant term, it must be mapped to itself by \(GR\). Then, \(GR\) must preserve 1, otherwise \(J_1 \neq J_{\sigma(1)}\) as \(k > t + 1\) or \(s > 2\). Furthermore, \(GR\) must also preserve the set \(\{y : d(1,y) > t\}\). Let \(GR'\) be the subgroup of \(GR\) consisting of all permutations that only permute the variables of the facet defining inequalities in Theorem 4 without changing their coefficients. Then \(GR'\) must preserve the coefficients \(\left(\frac{d(1,y) - d(1,1) - 1}{t - d(1,1)}\right)\) for \(\{y : d(1,y) > t\}\). Hence,

\[
d(1,y) = d(\tau(1), \tau(y)) = d(1, \tau(y)) \quad \text{if} \quad d(1,y) > t
\]

for all \(\tau \in GR'\). Since \(GR' \leq GR\), this leads to

\[
d(1,y) = d(\tau(1), \tau(y)) = d(1, \tau(y)) \quad \text{if} \quad d(1,y) \leq t.
\]

This shows that all elements in \(GR'\) are rotations around 1.

Let \(T = \{u \in [s]^k : d(u, 1) = 1\}\). Then \(|T| = (s - 1)k\) and \(|J_u| = s^{k-1}\) for each \(u \in T\). Since each \(\tau \in GR'\) is an invertible rotation around 1,

\[
\tau(T) = \{\tau(u) : u \in T\} = T \quad \text{for all} \quad \tau \in GR',
\]

34
and consequently

$$\{ J_\mathbf{u} : \mathbf{u} \in T \} = \{ J_{\tau(\mathbf{u})} : \mathbf{u} \in T \} \quad \text{for all } \tau \in GR'. \quad (3.7)$$

For $x, y \in [s]$, let $r_1(x, y)$, $r_2(x, y)$, $r_3(x, y)$, and $r_4(x, y)$ be the number of $\mathbf{u} \in T$ such that $x, y \in J_\mathbf{u}$, $x \notin J_\mathbf{u}$, $y \notin J_\mathbf{u}$, and $x \in J_\mathbf{u}$, $y \in J_\mathbf{u}$ respectively. Let

$$W = \begin{bmatrix} x \\ y \end{bmatrix}$$

and $a_1, a_2, a_3, a_4, a_5 \in \{2, \cdots, s\}$ such that $a_4 \neq a_5$. Now, let $\alpha_1(x, y), \alpha_2(x, y), \alpha_3(x, y), \alpha_4(x, y), \alpha_5(x, y)$ be the number of columns in $W$ of the form

$$\begin{bmatrix} 1 \\ 1 \\ a_1 \\ 1 \\ a_2 \\ a_3 \\ a_4 \\ a_5 \end{bmatrix}$$

respectively. Then,

$$r_1(x, y) = \alpha_4(x, y),$$

$$r_2(x, y) = k(s - 1) - (r_1(x, y) + r_3(x, y) + r_4(x, y)),$$

$$r_3(x, y) = \alpha_3(x, y) + \alpha_5(x, y),$$

$$r_4(x, y) = \alpha_2(x, y) + \alpha_5(x, y). \quad (3.8)$$

By (3.6) and (3.7), one can see that

$$r_i(x, y) = r_i(\tau(x), \tau(y)), \quad (3.9)$$

for all $\tau \in GR'$ and $i = 1, 2, 3, 4$.

Let $R_i(x')$ be the set of all $x$ obtained from $x' \in \{2, \cdots, s\}^k$ by replacing exactly $i$ coordinates in $x'$ with 1. Let $B(x') = \bigcup_{i=0}^k R_i(x')$ and $B(x')$ be the matrix whose $(\sum_{j=0}^{i-1} \binom{k}{j} + 1)$th row to $(\sum_{j=0}^{i} \binom{k}{j})$th row be the elements of $R_i(x')$ in some order. Then, the multiset

$$\bigoplus_{x' \in \{2, \cdots, s\}^k} B(x')$$

35
Let $GR$ permute the columns of $B$. Then by Lemma 3 each element $\tau$ of $GR$ is a permutation of columns of $B$. Furthermore, $|B(x') \cap B(y')| = 2^{(k-d(x',y'))}$, the $i$th column of $B(x')$ has only 1 and $x'[i]$ as its entries and consequently for any pair $x, y \in B(x')$, $\alpha_5(x, y) = 0$. Then, equations (3.8) and (3.9) imply that $\alpha_i(x, y)$ for $i = 1, 2, 3, 4, 5$ remain invariant under the action of $GR'$. Hence, 

$$d(x, y) = d(\tau(x), \tau(y)) = \alpha_2(x, y) + \alpha_3(x, y) + \alpha_5(x, y)$$  \hspace{1cm} (3.10)

for all $x, y \in B(x')$ and $\tau \in GR'$. 

Let $\tau(B(x')) = \{\tau(x) : x \in B(x')\}$. Since each $\tau \in GR'$ is a rotation permutation around 1 that preserves distances between the elements of $B(x')$, it is apparent that $\tau(B(x')) = B(\tau(x'))$. Let $\overline{B(x')} = [2]^k$ and $\overline{x}$ be obtained from $B(x')$ and $x$ by replacing the non-one entries with 2 respectively. Then for each $x' \in \{2, \cdots, s\}$,

$$d(x, y) = d(\overline{x}, \overline{y})$$ \hspace{1cm} (3.11) 

Let $GR'$ act on $\overline{B(x')}$ by $\tau(\overline{x}) = \overline{\tau(x)}$. Then, since $\tau(B(x')) = B(\tau(x'))$ by (3.11),

$$d(\tau(x), \tau(y)) = d(\overline{\tau(x)}, \overline{\tau(y)}),$$  \hspace{1cm} (3.12)

and

$$\{\tau(\overline{x}) : x \in B(x')\} = \{\tau(\overline{x}) : x \in B(x')\} = \overline{\tau(B(x'))} = \overline{B(\tau(x'))} = [2]^k.$$  \hspace{1cm} (3.13)

Now, (3.10), (3.11) and (3.12) lead to

$$d(\tau(\overline{x}), \tau(\overline{y})) = d(\overline{\tau(x)}, \overline{\tau(y)}) = d(\tau(x), \tau(y)) = d(x, y) = d(\overline{x}, \overline{y}).$$  \hspace{1cm} (3.14)

for all $x, y \in B(x')$. Hence, by (3.13) and (3.14) $GR'$ acts on $\overline{B(x')} = [2]^k$ as rotation isometries. Then by Lemma 3 each element $\tau$ of $GR'$ acting on the elements of the set $\overline{B(x')}$ can be written as $\tau = \gamma^x$, where $\gamma^x$ is a permutation of columns of $\overline{B(x')}$. Let $\gamma^x$ permute the columns of $B(x')$ the same way it permutes the columns of $\overline{B(x')}$. Also, let
\( \mu^x = (\gamma^x)^{-1} \tau \) then \( \mu^x(x) = (\gamma^x)^{-1} \tau(x) = \overline{x} \) for each \( x \in B(x') \). This implies that \( \mu^x \) only changes the non-one elements to non-one elements in the rows of \( B(x') \). Since,

\[
d(x, y) = d(\tau(x), \tau(y)) = d((\gamma^x)^{-1} \tau(x), (\gamma^x)^{-1} \tau(y)) = d(\mu^x(x), \mu^x(y))
\]

for all \( x, y \in B(x') \), and \( \mu^x \) fixes \( 1 \), \( \mu^x \) is a rotation around \( 1 \) and an isometry on the set \( B(x') \). Let \( \mu^x(B(x')) = \cup_{i=0}^{k} \mu^x(R_i(x')) \) and \( \mu^x(B(x')) \) be the matrix whose \( (\sum_{j=0}^{k-1} \binom{k}{j} + 1) \)th row to \( (\sum_{j=0}^{l} \binom{k}{j}) \) th row be the elements of \( \mu^x(R_i(x')) \) in some order, where \( \mu^x(R_i(x')) \) is the set obtained by applying \( \mu^x \) elementwise. Now, for \( j = 1, \cdots, k \), the non-one entry appearing in the \( j \) th column of \( B(x') \) must be mapped by \( \mu^x \) to the same non-one element every time it appears. Otherwise, \( \mu^x \) is not an isometry rotation around \( 1 \) on the set \( B(x') \). Hence, by taking \( \tau^x = \gamma^x \mu^x \) one can deduce that there exists some \( \tau^x \in S_{[2, \cdots, s]} \wr S_k \) such that

\[
\tau(x) = \tau^x(x)
\]

for all \( x \in B(x') \) and \( \tau \in GR' \). Next, it is shown that proving the following claim is sufficient.

**Claim:** There exists some \( \tau^{\text{full}} \in S_{[2, \cdots, s]} \wr S_k \) acting on \( [s]^k \) such that, for each \( x' \in [2, \cdots, s]^k \), \( \tau^{\text{full}}(x) = \tau^x(x) = \tau(x) \) for all \( x \in B(x') \).

First, the claim implies that \( \tau \in S_{[2, \cdots, s]} \wr S_k \) for arbitrary \( \tau \in GR' \). Then, \( |GR'| \leq |S_{(s-1) \wr S_k} | \).

By Theorem 7, \( GR' \) contains an isomorphic copy of \( S_{(s-1) \wr S_k} \) as a subgroup as \( 0 < t < k \) was assumed and \( (k > t + 1 \) or \( s > 2 ) \). Hence, \( GR' = H_{k,s,t} \equiv S_{(s-1) \wr S_k} \). Now, it is clear that \( \Pi(OAP(k, s, t, \lambda)) = GR'_{[\{ y: d(1,y) > t \}} \), where \( GR'_{[\{ y: d(1,y) > t \}} \) is the restriction of \( GR' \) to variables \( \{ y : d(1,y) > t \} \). Finally, since \( GR' \) preserves the set \( \{ y : d(1,y) > t \} \), no permutations are lost by restricting \( GR' \). Hence, \( \Pi(OAP(k, s, t, \lambda)) = GR'_{[\{ y: d(1,y) > t \}} = H_{k,s,t} \equiv S_{(s-1) \wr S_k}. \)

**Proof of the Claim:** Let \( x'_1, x'_2 \in [2, \cdots, s]^k \) be such that \( x'_1 \) and \( x'_2 \) are different only on the \( l \) th coordinate. Let \( B(x'_1, x'_2) \) be the matrix obtained by taking the elements in \( B(x'_1) \cap B(x'_2) \) as rows in some order. Then, the \( h \) th column of \( B(x'_1, x'_2) \) is the column of all 1s and the \( j \) th column of \( B(x'_1, x'_2) \) for \( j \neq l \) has only entries from the set \( \{ 1, x'_1[j] \} \), where \( x'_1[j] = x'_2[j] \) is
the $j$th entry of $\mathbf{x}_1'$. Furthermore, $\mathbf{B}(\mathbf{x}_1', \mathbf{x}_2')^{-l}$ consists of all $2^{k-1}$ non-one combinations, where $\mathbf{B}(\mathbf{x}_1', \mathbf{x}_2')^{-l}$ is obtained from $\mathbf{B}(\mathbf{x}_1', \mathbf{x}_2')$ by deleting its $l$th column.

Now write

$$\tau(\mathbf{x}) = \begin{cases} 
\tau^{x_1}(\mathbf{x}) = \gamma^{x_1} \mu^{x_1}(\mathbf{x}) & \text{if } \mathbf{x} \in B(\mathbf{x}_1'), \\
\tau^{x_2}(\mathbf{x}) = \gamma^{x_2} \mu^{x_2}(\mathbf{x}) & \text{if } \mathbf{x} \in B(\mathbf{x}_2'), 
\end{cases}$$  \hspace{1cm} (3.15)

where $\gamma^{x_1}(\mathbf{x})$ is a permutation of columns of $\mathbf{x}$ and $\mu^{x_1}(\mathbf{x})$ only changes the non-one elements in the columns of $\mathbf{B}(\mathbf{x}_1')$. First, $\gamma^{x_1}, \mu^{x_1} \in S_{\{2, \ldots, s\}} \times S_k$. Secondly,

$$\tau^{x_1}(\mathbf{x}) = \tau^{x_2}(\mathbf{x}) = \tau(\mathbf{x})$$

for all $\mathbf{x} \in \mathbf{B}(\mathbf{x}_1', \mathbf{x}_2')$. Hence, $\mu^{x_2} \gamma^{x_2}(\mathbf{x}) = \gamma^{x_2} \mu^{x_2}(\mathbf{x}) = \mu^{x_1} \gamma^{x_1}(\mathbf{x}) = \gamma^{x_1} \mu^{x_1}(\mathbf{x})$ for all $\mathbf{x} \in \mathbf{B}(\mathbf{x}_1', \mathbf{x}_2')$. This implies that

$$\gamma^{x_1}(\bar{\mathbf{x}}) = \gamma^{x_2}(\bar{\mathbf{x}}) \quad \text{for } \bar{\mathbf{x}} \in \overline{\mathbf{B}(\mathbf{x}_1', \mathbf{x}_2')}.$$  \hspace{1cm} (3.16)

Since $\overline{\mathbf{B}(\mathbf{x}_1', \mathbf{x}_2')}$ is $[2]^{k-1}$ with an all 1s column attached to it, columns of $\overline{\mathbf{B}(\mathbf{x}_1', \mathbf{x}_2')}$ are distinguishable. Hence, equation (3.16) completely (uniquely) determines how columns of $\mathbf{x}$ are permuted by

$$\gamma^{x_1}(\mathbf{x}) = \gamma^{x_2}(\mathbf{x}) \quad \text{for } \mathbf{x} \in B(\mathbf{x}_1') \cup B(\mathbf{x}_2').$$  \hspace{1cm} (3.17)

Now, one can see that

$$\mu^{x_1}(\mathbf{x}) = \mu^{x_2}(\mathbf{x}) \quad \text{for } \mathbf{x} \in B(\mathbf{x}_1', \mathbf{x}_2'). \hspace{1cm} (3.18)$$

Then, $\mu^{x_1}((\mathbf{x})^{-l}) = \mu^{x_2}((\mathbf{x})^{-l})$ for each $(\mathbf{x})^{-l}$ appearing as a row of $\begin{bmatrix} \mathbf{B}(\mathbf{x}_1')^{-l} \\ \mathbf{B}(\mathbf{x}_2')^{-l} \end{bmatrix}$ as $B(\mathbf{x}_j')^{-l} = B(\mathbf{x}_j')^{-l}$, where $B(\mathbf{x}_j')^{-l}$ is the set of rows of $\mathbf{B}(\mathbf{x}_j')^{-l}$ for $j = 1, 2$. Now, extend the domain of $\mu^{x_1}$ from $B(\mathbf{x}_1')$ to $B(\mathbf{x}_1') \cup B(\mathbf{x}_2')$ by setting

$$\mu^{x_1}_{\text{ext}}(\mathbf{x}) = \begin{cases} 
\mu^{x_1}(\mathbf{x}) & \text{if } \mathbf{x} \in B(\mathbf{x}_1'), \\
\mu^{x_2}(\mathbf{x}) & \text{if } \mathbf{x} \in B(\mathbf{x}_2'). 
\end{cases}$$  \hspace{1cm} (3.19)

By equation (3.18) this extension is well defined.

38
Next, it is shown that $\mu_{\text{ext}}^{x_i}(x)$ is injective and that $\mu_{\text{ext}}^{x_i}(x) \in S_{\{2, \ldots, s\}} \subset S_{\{2, \ldots, s\}} \triangleleft S_k$. First, by the preceding arguments, $\mu_{\text{ext}}^{x_i}$ acts on $\left[ \frac{B(x'_i)^j}{B(x'_j)^j} \right]$ as an element of $S_{\{2, \ldots, s\}}^{k-1}$. Hence, it suffices to show that $\mu_{\text{ext}}^{x_i}$ acts on $\left[ \frac{B(x'_i)^j}{B(x'_j)^j} \right]$ as an element of $S_{\{2, \ldots, s\}}$ and $\mu_{\text{ext}}^{x_i}$ is injective, where $B(x'_i)^j$ is the $j$th column of $B(x'_i)$. Note that $\mu_{\text{ext}}^{x_i}$ fixes 1 in every column of $B(x'_i)$. Hence, $\mu_{\text{ext}}^{x_i}$ fixes 1 in every column of $\left[ \frac{B(x'_i)^j}{B(x'_j)^j} \right]$ and consequently in $\left[ \frac{B(x'_i)^j}{B(x'_j)^j} \right]$. Furthermore, since each $\mu_{\text{ext}}^{x_i}$ must map each non-one entry in $B(x'_i)^j$ to the same non-one element in $[s]$, so does $\mu_{\text{ext}}^{x_i}$. Hence, $\mu_{\text{ext}}^{x_i}$ acts on $\left[ \frac{B(x'_i)^j}{B(x'_j)^j} \right]$ as an element of $S_{\{2, \ldots, s\}}$. Now by equations (3.15), (3.17) and (3.19), one can see that

$$\mu_{\text{ext}}^{x_i}(x) = (\gamma x_i^{-1}) \tau(x) \quad \text{for } x \in B(x'_1) \cup B(x'_2).$$

Injectivity of $\mu_{\text{ext}}^{x_i}$ follows from equation (3.20). Now, extend the domain of $\tau^{x_i}(x)$ for $x \in B(x'_1)$ with $B(x'_2)$ by defining

$$\tau^{x_i}_{\text{ext}}(x) = \gamma x_i^{x_i} \mu_{\text{ext}}^{x_i}(x) \quad \text{for } x \in B(x'_1) \cup B(x'_2).$$

To finish the proof, notice that there exists a finite sequence $\{x'_i\}_{i=1}^m$ such that $d(x'_i, x'_{i+1}) = 1$ and

$$\bigcup_{i=1}^m \{x'_i\} = \{2, \ldots, s\}^k,$$

where $x'_i$ are not necessarily distinct. Extend the domain of $\tau^{x_i}$ along this sequence. It is understood that an extension in the domain is made only for $x'_i$ appearing for the first time. Let $\tau_{\text{full}}$ be the resulting map. Since each extension is injective, acts as an element of $S_{\{2, \ldots, s\}} \triangleleft S_k$ in its extended domain, and the domain of $\tau_{\text{full}}$ is

$$\bigcup_{i=1}^{(s-1)^k} B(x'_i) = [s]^k,$$

$\tau_{\text{full}}$ acts on $[s]^k$ as an element of $S_{\{2, \ldots, s\}} \triangleleft S_k$.

\[\square\]

**Theorem 9.** Unless $t = 0$ or $t = k$, $G_{s,k} \cong S_s \wr S_k$ in Theorem 9 of Bulutoglu and Margot [7] is the largest subgroup of $S_{\varphi}$ that sends equations (3.3) to themselves. For $t = 0$ or $t = k$ the largest such group is $S_{\varphi}$.  

39
Proof. First, consider the case when $0 < k - t < k$. Let $G$ be the group of all coordinate permutations of $[s]^k$ which permute the rows of the constraint matrix $A$ pertaining to equations (3.3) in the full space $\mathbb{R}^d$. It was shown in Bulutoglu and Margot [7] that $G$ contains $G_{s,k}$ as a subgroup. Hence, it suffices to show that $G \leq G_{s,k}$. First, it is shown that every element in $G$ is an isometry.

Let $\sigma \in G$ and $z \in [s]^k$. Since $G_{s,k}$ acts transitively on $[s]^k$ and itself consists of isometries, one may assume $\sigma(z) = z$. Consider the set $S$ of all rows of $A$ in which $z$ appears. Since $\sigma(z) = z$, $\sigma$ must permute $S$. Let $w \in [s]^k$ be such that $d(z, w) = i$, where $i \in \{0, 1, \cdots, k - t\}$. Then $w$ appears in exactly $\binom{k - i}{i}$ rows in $S$. Since $\sigma$ preserves $S$, $\sigma(w)$ also appears in exactly $\binom{k - i}{i}$ rows in $S$. Then one must have $d(z, \sigma(w)) = i$ as no element is repeated in the set $\{\binom{k - i}{i}_i \}$ of $S$. Hence, $d(z, w) = d(\sigma(z), \sigma(w))$ for all $z$ and $w$ such that $0 \leq d(z, w) \leq k - t$.

Now, for any $z$ and $y$ such that $d(z, y) = k - t + 1$ there exists $y_1$ such that $d(z, y) = d(z, y_1) + d(y_1, y)$, where $d(z, y_1) = k - t$ and $d(y_1, y) = 1 \leq k - t$. By the triangle inequality $d(\sigma(z), \sigma(y)) \leq d(\sigma(z), \sigma(y_1)) + d(\sigma(y_1), \sigma(y)) = k - t + 1 = d(z, y)$. By repeating the same argument for $z$ and $y$ such that $d(z, y) = k - t + i$ for $i = 2, \cdots, t$,

$$d(\sigma(z), \sigma(y)) \leq d(z, y) \quad (3.21)$$

for all $z, y$ and $\sigma$. Let $z' = \sigma(z)$, $y' = \sigma(y)$ and $h = \sigma^{-1}$ then

$$d(z', y') \leq d(h(z'), h(y')) \quad (3.22)$$

for all $z', y'$ and $h$. Combining inequalities (3.21) and (3.22) leads to

$$d(\sigma(z), \sigma(y)) = d(z, y)$$

for all $z, y \in [s]^k$ and $\sigma \in G$. Hence, by Lemma 3, an isomorphic copy of $G$ is contained in $S_{s} \wr S_{k}$. Now, this implies that $G \leq G_{s,k} \cong S_{s} \wr S_{k}$. The cases $t = 0$ and $t = k$ are easy to see.
IV. Computational Research

4.1 Chapter Introduction

As discussed in Section 2.5, Margot [23] defined the symmetry group of an LP to be the set of all permutations of the variables of an LP that send feasible points to feasible points with the same objective function value. Margot [23] and Ostrowski et al. [27] defined the symmetry group of an ILP to be the set of all permutations of the variables that map a feasible solution to a feasible solution with the same objective value. Let the symmetry group of ILP (2.4) be

$$G(k, s, t) = \{ \pi \in S_{\phi} \mid \pi(x) \in \mathcal{F}(k, s, t) \}$$

and the symmetry group of ILP (3.2) be

$$G'(k, s, t) = \{ \pi \in S_{\phi-m} \mid \pi(x) \in \mathcal{F}'(k, s, t) \}.$$ 

Let $T$ be the set of deleted variables to get ILP (3.2) from ILP (2.4). It is not hard to see that $\text{stab}(T, G_{s,k})$ is the set of all permutations that permute indices of $x'$ by permuting coordinates in $(\alpha_1^j + 1, \alpha_2^j + 1, \cdots, \alpha_k^j + 1)$ and/or by independently sending a subset of non-one coordinates to non-one coordinates. Hence $|\text{stab}(T, G_{s,k})| = (s-1)!^kk!$. Let $G(A(k, s, t), \lambda \mathbf{1})^{LP}$ and $G(A'(k, s, t), b)^{LP}$ denote the LP relaxation symmetry groups of ILP (2.4) and ILP (3.2) respectively. Let $G(A, b)$ be as in equation (2.15) in Section 2.4 with $c = \mathbf{1}$ and $d = p_{\max} \mathbf{1}$. Recall from Section 3.3 that $\text{stab}(T, G_{s,k}) = G(A'(k, s, t), b)$ and $G_{s,k} = G(A(k, s, t), \lambda \mathbf{1})$. These results imply that $|G'(k, s, t)| \geq |G(A'(k, s, t), b)| = (s-1)!^kk!$ and $|G(k, s, t)| \geq |G_{s,k}| = |G(A(k, s, t), \lambda \mathbf{1})| = s!^kk!$.

In Section 3.2, it is shown that all the inequalities in the LP relaxation of ILP (3.2) are facets. Hence, by the Margot [23] symmetry group definition, this implies that $G(A'(k, s, t), b)^{LP} = G(A'(k, s, t), b) \cong S_{\{2,3,\cdots,s\}} \wr S_k$. However, since ILP (2.4) has equality constraints it is not clear whether $G(A(k, s, t), \lambda \mathbf{1}) = G(A(k, s, t), \lambda \mathbf{1})^{LP}$ or not. The most that can be said presently is that $G(A(k, s, t), \lambda \mathbf{1}) \subseteq G(A(k, s, t), \lambda \mathbf{1})^{LP}$. In Section 4.2 an
efficient, practical method for computing $G(\mathbf{A}(k, s, t), \lambda \mathbf{1})^{LP}$ is developed and implemented. It is observed that for $1 \leq t \leq k - 1$

$$|G(\mathbf{A}(k, s, t), \lambda \mathbf{1})^{LP}| = \begin{cases} (k + 1)|G(\mathbf{A}(k, s, t), \lambda \mathbf{1})| = (k + 1)!2^k & s = 2 \text{ and even } t, \\ |G(\mathbf{A}(k, s, t), \lambda \mathbf{1})| = k! (s!)^k & \text{otherwise.} \end{cases}$$

For $s = 2$ and even $t$, using the larger symmetry group drastically reduces solution times. In fact, in all almost all cases considered, deleting variables from the ILP (2.5) formulation to get the ILP (3.2) formulation proved to be counterproductive. The reason for this is that for $1 \leq t \leq k - 1$

$$|G(\mathbf{A}(k, s, t), \lambda \mathbf{1})| = s^k |G(\mathbf{A}'(k, s, t), \mathbf{b})|$$

and

$$|G(\mathbf{A}(k, s, t), \lambda \mathbf{1})^{LP}| = \begin{cases} (k + 1) 2^s |G(\mathbf{A}'(k, s, t), \mathbf{b})| & s = 2 \text{ and even } t, \\ s^k |G(\mathbf{A}'(k, s, t), \mathbf{b})| & \text{otherwise.} \end{cases}$$

Hence, exploiting a larger symmetry group more than overcomes the additional computational burden of having a larger number of variables. This underscores the importance of developing tools for finding larger subgroups of the full symmetry group of an ILP.

As discussed in Section 2.5, whenever the Margot [22] isomorphism pruning algorithm is used for solving a symmetric ILP in the form of ILP (2.14) or ILP (2.16), $G(\mathbf{A}, \mathbf{b})^{LP}$ or a subgroup of $G(\mathbf{A}, \mathbf{b})^{LP}$ is used for isomorphism pruning. However, when the goal is to find at least one OA($N, k, s, t$) for a given $N, k, s, t$ or to prove that no OA($N, k, s, t$) exists, it is viable to use $\mathcal{G}(k, s, t)$ ($\mathcal{G}'(k, s, t)$) instead of $G(\mathbf{A}(k, s, t), \lambda \mathbf{1})^{LP}$ ($G(\mathbf{A}'(k, s, t), \mathbf{b})^{LP}$). This will yield significant increases in computational efficiency if $|\mathcal{G}(k, s, t)|$ ($|\mathcal{G}'(k, s, t)|$) is much larger than $|G(\mathbf{A}(k, s, t), \lambda \mathbf{1})^{LP}|$ ($|G(\mathbf{A}'(k, s, t), \mathbf{b})^{LP}|$). Hence, one open, fundamental question regarding ILP (2.5) is: How much larger is $|\mathcal{G}(k, s, t)|$ ($|\mathcal{G}'(k, s, t)|$) than $|G(\mathbf{A}(k, s, t), \lambda \mathbf{1})^{LP}|$ ($|G(\mathbf{A}'(k, s, t), \mathbf{b})^{LP}|$)? A method for computing $\mathcal{G}(k, s, t)$ is given in Section 4.4. This method requires all possible solutions to ILP (2.5) as an input. Hence, it cannot be used for solving unsolved problems. However, it
is a good diagnostic test telling us how close we are to exploiting all possible symmetries of ILP (2.5) when $G(A(k, s, t), \lambda 1)^{LP}$ is used with Margot [22] isomorphism pruning algorithm. One interesting question that is investigated is how the number of isomorphism classes of solutions to ILP (2.5) and ILP (3.2) compare using $G(A(k, s, t), \lambda 1)^{LP}$ and $G(A'(k, s, t), b)^{LP}$, respectively.

In Section 4.3, the Section 4.2 method is generalized and the generalized method is tested on the MILP library problems studied in Liberti [18].

The improvements in Section 4.5 enable the use of Margot [22] isomorphism pruning solver in the algorithm in Figure 2.4 ILP formulation without losing OD classes or isomorphism classes of OA($N, k, s, t$). Also, a previously unknown large subgroup of $G(A(k, 2, t), \lambda 1)^{LP}$ is found.

All computations in this chapter were performed on an HP Z820 workstation with 64GB of RAM and a 3.10 GHz Intel Xeon E5-2687W processor.

4.2 Research Objective 1

4.2.1 Computing $G(A(k, 2, t), \lambda 1)^{LP}$.

Every solution to the LP relaxation of ILP (2.4) can be written in the form

$$p_{\text{max}} 1 \geq x = \frac{\lambda}{\hat{x}} + v \geq 0$$

for some $v \in \text{Null}(A(k, s, t)) \cap \left[\frac{-\lambda}{\hat{x}}, p_{\text{max}} - \frac{\lambda}{\hat{x}}\right]^s$. This is true because $s^{t-k} 1$ is a particular solution and $x \geq 0$. Since any permutation of $s^k$ coordinates preserves $\left[\frac{-\lambda}{\hat{x}}, p_{\text{max}} - \frac{\lambda}{\hat{x}}\right]^s$, $G(A(k, s, t), \lambda 1)^{LP}$ is the set of all permutations in $S_{s^k}$ that preserve the elements of $\text{Null}(A(k, s, t))$. Null($A(k, s, t)$) is the orthogonal complement of the row space of $A(k, s, t)$, hence the same set is also characterized as the set of all permutations that stabilize the row space of $A(k, s, t)$. Such a set is computed as the automorphism group of $P_{A^T(k, s, t)}$, where

$$P_{A^T(k, s, t)} = A^T(k, s, t)\left(A(k, s, t)A^T(k, s, t)\right)^{-1}A(k, s, t)$$  (4.1)
is the orthogonal projection matrix on to the row space of $A(k, s, t)$, and $\left( A(k, s, t)A^T(k, s, t) \right)^+$ is the Moore-Penrose pseudoinverse of $A(k, s, t)A^T(k, s, t)$ [17]. The automorphism group of $P_{A^T(k,s,t)}$ is the set of all $\pi \in S_{s^k}$ that send $P_{A^T(k,s,t)}$ to itself when rows and columns of $A^T(k, s, t)$ are permuted according to $\pi$. This automorphism group is computed as the automorphism group of an edge colored graph with $s^k$ vertices. Each distinct entry in $P_{A^T(k,s,t)}$ is labeled with a distinct color. There is an edge between $i$th and $j$th vertices labeled with color $l$, if and only if the $(i, j)$th entry of $P_{A^T(k,s,t)}$ is labeled with color $l$.

Let $A(k, s, t)$ be $m \times n$ (where $n = s^k$), $p = \text{rank}(A(k, s, t))$, and $A(k, s, t) = UDV^T$ be the singular value decomposition of $A(k, s, t)$. Then, by using the results in [17], equation (4.1) simplifies to
\begin{equation}
P_{A^T(k,s,t)} = VI_n^{(p)}V^T,
\end{equation}
where
\[
I_n^{(p)} = \begin{bmatrix} I_{p \times p} & 0_{p \times (n-p)} \\ 0_{(n-p) \times p} & 0_{(n-p) \times (n-p)} \end{bmatrix}.
\]
Equation (4.2) was used to calculate $P_{A^T(k,s,t)}$ as it requires fewer floating point operations, leading to improved accuracy.

The automorphism group of $P_{A^T(k,s,t)}$ was computed by using Nauty, where edge coloring was implemented as described in McKay [25]. $G(A(k, s, t), \lambda 1)^{LP}$ was computed for many $k, s, t$ combinations by using the aforementioned method. In all cases considered, $G(A(k, s, t), \lambda 1)^{LP} \subseteq G(A(k, s, t), \lambda 1)^{LP}$ for $s = 2$ and even $t$, and $G(A(k, s, t), \lambda 1) = G(A(k, s, t), \lambda 1)^{LP}$ otherwise. Consequently, for $s = 2$ and even $t$, using the group $G(A(k, s, t), \lambda 1)^{LP}$ significantly decreased solution times. This method generalizes the concept of $G(A, b)^{LP}$ first defined in Margot [23]. A further generalization of this method that finds $G(A, b)^{LP}$ for arbitrary $A$ and $b$, where a particular solution with equal coordinates is not available, is developed in Section 4.3.

ILP (2.5) was solved for many $k, s, t$ combinations using the groups $G(A(k, s, t), \lambda 1)^{LP}$ and $G(A(k, s, t), \lambda 1)^{LP}$. This is legitimate as ILPs (2.4) and (2.5) have the same feasible
ILP (3.2) was solved for the same \( k, s, t \) combinations using \( G(A'(k, s, t), b)^{\text{LP}} \). A speed comparison of these three formulations using Margot ILP solver \([22]\) is made in Table 4.1. For each \( \text{OA}(N, k, s, t) \), the second, third and fourth columns report the number of solutions enumerated for ILP (2.5) using \( G(A(k, s, t), \lambda \textbf{1}) \), ILP (2.5) using \( G(A(k, s, t), \lambda \textbf{1})^{\text{LP}} \), and ILP (3.2) using \( G(A'(k, s, t), b)^{\text{LP}} \). Likewise, the fifth, sixth and seventh columns report the time it took to enumerate these solutions. Even though ILP (3.2) has fewer variables, computational experiments summarized in Table 4.1 suggest that it should not be preferred over ILP (2.5). It is evident from Table 4.1 that exploiting the larger symmetry group more than overcomes the additional computational burden of having a larger number of variables. In fact, the computational savings appear to grow exponentially with the number of variables. On the other hand, the cases \( \text{OA}(64, 7, 2, 4) \) and \( \text{OA}(24, 11, 2, 3) \) do buck this trend.

The code used to compute column 2 of Table 4.1 is found in Bulutoglu and Ryan [8]. The code used to compute column 3 via modification of the Bulutoglu and Ryan [8] code is
found in Section B.1. The code used to compute column 4 via modification of the Bulutoglu and Ryan [8] is found in Section B.2.

### 4.2.2 Finding a Large Subgroup of $G(A(k, 2, t), \lambda 1)^{LP}$

Switch to $\pm 1$ coding of the $2^k$ full factorial design using the function

$$
(x_1, x_2, \cdots, x_k)^T \xrightarrow{\phi_1} ((-1)^{x_1}, (-1)^{x_2}, \cdots, (-1)^{x_k})^T
$$

if $(x_1, x_2, \cdots, x_k)^T \in \{0, 1\}^k$ and

$$
(x_1, x_2, \cdots, x_k)^T \xrightarrow{\phi_2} ((-1)^{x_1-1}, (-1)^{x_2-1}, \cdots, (-1)^{x_k-1})^T
$$

if $(x_1, x_2, \cdots, x_k)^T \in \{1, 2\}^k$. Both $\phi_1$ and $\phi_2$ are invertible functions. So, we can switch between $\{0, 1\}$, $\{1, 2\}$ and $\{\pm 1\}$ codings as necessary. Let $N_x^k$, $N_x^k$ and $N_x^k$ be the number of times $x \in \{0, 1\}^k$, $x' \in \{1, 2\}^k$ and $x'' \in \{\pm 1\}^k$ appears in a sought after $k$-factor factorial design. Let $N_x^s$, $N_x^s$ and $N_x^s$ be the $s \times 1$ vectors whose $x$th, $x'$th and $x''$th variables are $N_x^s$, $N_x^s$ and $N_x^s$. Functions $\phi_1$ and $\phi_2$ are chosen so as to preserve the ordering of the variables in $N_x^s$, $N_x^s$ and $N_x^s$ in such a way that 0, 1 and 1 are the low levels in the $\{0, 1\}$, $\{1, 2\}$ and $\{\pm 1\}$ codings.

Let $X_{2^k}^s = (x_{ij}^s)$ be the full factorial $2^k$ design in $\{-1, 1\}$ coding. For an indicator vector $N_x^{s''} \in \mathbb{R}^{2^k}$ with $N_x^{s''} \geq 0$, define

$$
J_{\{j_1, j_2, \cdots, j_p\}} = \sum_{i=1}^{2^k} x_{ij_1}^s x_{ij_2}^s \cdots x_{ij_p}^s N_x^{s''}(x_{ij_1}^s, x_{ij_2}^s, \cdots, x_{ij_p}^s),
$$

$$
J_{\emptyset} = \sum_{i=1}^{2^k} N_x^{s''}(x_{ij_1}^s, x_{ij_2}^s, \cdots, x_{ij_p}^s),
$$

(4.3)

Then, $J_{\{j_1, j_2, \cdots, j_p\}}$ is called the $J$-characteristic of length $p$ of $N^s$ [32].

**Theorem 10.** $N_x^{s''}$ is the indicator vector of an OA($N, k, 2, t$) if and only if $N_x^{s''} \in \mathbb{Z}_{\geq 0}^{2^k}$ and

$$
J_{\emptyset} = \sum_{i=1}^{2^k} N_x^{s''}(x_{ij_1}^s, x_{ij_2}^s, \cdots, x_{ij_p}^s) = N,
$$

(4.4)

$$
J_{\{j_1, j_2, \cdots, j_p\}} = \sum_{i=1}^{2^k} x_{ij_1}^s x_{ij_2}^s \cdots x_{ij_p}^s N_x^{s''}(x_{ij_1}^s, x_{ij_2}^s, \cdots, x_{ij_p}^s) = 0,
$$

47
for all size p subsets \( \{j_1, j_2, \cdots, j_p\} \) of \( \{1, 2, \cdots, k\} \) and all \( p \in \{1, 2, \cdots, t\} \) \[32\].

For each equation in (4.4) whose right hand side is zero, multiply both sides by \(-1\) and append it to (4.4). Let \( G^J_{k,t} \) be the automorphism group of the resulting system of equations. Theorem 10 implies that every equation in ILPs (2.4) and (2.5) is a linear combination of equations in (4.4). Hence, \( G^J_{k,t} \leq G(\mathbf{A}(k,2,t), \mathbf{A})^{LP} \). \( S_2 \triangleleft S_k \) acts on \( \mathbf{x''} \) as signed permutations of columns of \( \mathbf{x''} \), where \( \mathbf{x''} \) is a row of \( \mathbf{X}''_2^k \). For a given indicator vector \( \mathbf{N}'' \), this action extends to an action on \( J\)-characteristics of \( \mathbf{N}'' \) via equation (4.3). \( S_2 \triangleleft S_k \) acts as signed permutations on \( J\)-characteristics of \( \mathbf{N}'' \) as well. Hence, \( S_2 \triangleleft S_k \leq G^J_{k,t} \).

For each row \( \mathbf{x''} = (x_1'', x_2'', \cdots, x_k'') \) of \( \mathbf{X}''_2^k \), let

\[
 a_f \mathbf{x''} = (x_{f,x_1''}^{(1)}, x_{f,x_2''}^{(2)}, \cdots, x_{f,x_{k-1}''}^{(p)}, x_{f,x_p''}^{(p-1)}, x_{f,x_p''}^{(p+1)}, \cdots, x_{f,x_k''}^{(1)}),
\]

for \( 1 \leq f \leq k \). Then, \( a_f \) permutes the variables \( N_{x''} \) by

\[
 N_{x''} \xrightarrow{a_f} N_{a_f x''}.
\]

This action extends to an action on \( J\)-characteristics of \( \mathbf{N}'' \), where

\[
 J_{\{j_1, j_2, \cdots, j_p\}} \xrightarrow{a_f} \sum_{i=1}^{2^k} (x_{i,f}^{(1)})^p x_{ij_1''}^{(1)} x_{ij_2''}^{(2)} \cdots x_{ij_p''}^{(p)} N(x_{i,f,x_1''}^{(1)}, x_{i,f,x_2''}^{(2)}, \cdots, x_{i,f,x_{p-1}''}^{(p)}, x_{i,f,x_p''}^{(p)}, x_{i,f,x_{p+1}''}^{(p)}, \cdots, x_{i,f,x_k''}^{(1)}).
\]

Each \( a_f \) acts as permutations of \( J\)-characteristics of \( \mathbf{N}'' \). Now, the following theorem follows.

**Theorem 11.** The action of \( a_f \) sends a \( J\)-characteristic of length \( p \) to a \( J\)-characteristic of length \( p \) if \( p \) is even and to a \( J\)-characteristic of length \( p + 1 \) if \( p \) is odd.

The following corrolary immediately follows from Theorem 11.

**Corrolary 1.** The action of \( a_f \) sends the extended system of equations (4.4) to itself if \( t \) is even. Hence, if \( t \) is even, \( a_f \in G^J_{k,t} \) and consequently \( \langle a_1, a_2, \cdots, a_k, S_2 \triangleleft S_k \rangle \leq G^J_{k,t} \), where \( \langle a_1, a_2, \cdots, a_k, S_2 \triangleleft S_k \rangle \) is the group generated by \( a_1, a_2, \cdots, a_k \) and \( S_2 \triangleleft S_k \).
Theorem 12. \(|(a_1, a_2, \cdots, a_k, S_2 \wr S_k)| = (k + 1)!2^k\)

Proof. Let \(G_k = \langle a_1, a_2, \cdots, a_k, S_2 \wr S_k \rangle\). Let \(D = [x_1, x_2, \cdots, x_k]\) be a \(k\) factor, 2 level, \(N\) run generic design. Let \(O\) be the orbit of of \(D\) under the action of \(G_k\). Each element of \(G_k\) is completely determined by its action on \(D\). Hence \(|G_k| = |O|\). For two vectors, \(x, y \in \mathbb{R}^k\), let \(x \odot y = (x_1y_1, x_2y_2, \cdots, x_ky_k)^T\). Let

\[
B_0 = \{x_1, x_2, \cdots, x_k\}
\]

and for \(i = 1, 2, \cdots, k\) let

\[
B_i = \{x_1 \odot x_i, x_2 \odot x_i, \cdots, x_{i-1} \odot x_i, x_i, x_{i+1} \odot x_i, \cdots, x_k \odot x_i\}.
\]

Then, for each \(i = 0, 1, 2, \cdots, k\) there exists an element in \(O\) whose set of columns is \(B_i\). Hence, \(|O| \geq 2^k(k + 1)!\). Observing that the set of columns (up to multiplication by \(\pm 1\)) of each element in \(O\) is equal to \(B_i\) for some \(i \in \{0, 1, \cdots, k\}\) finishes the proof. \(\square\)

Hence, for even \(t\) and \(s = 2, (k + 1)!2^k \leq |G_{k,t}^J|\). Based on computer observations, the following conjecture is made:

**Conjecture 1.**

\[
G_{k,t}^J = \begin{cases} 
(a_1, a_2, \cdots, a_k, S_2 \wr S_k) & \text{if } t \text{ is even and } 1 \leq t \leq k, \\
S_2 \wr S_k & \text{if } t \text{ is odd and } 1 \leq t \leq k, \\
S_2^k & \text{otherwise.}
\end{cases}
\]

Hence,

\[
|G_{k,t}^J| = \begin{cases} 
(k + 1)!2^k & \text{if } t \text{ is even and } 1 \leq t \leq k, \\
k!2^k & \text{if } t \text{ is odd and } 1 \leq t \leq k, \\
2^k & \text{otherwise.}
\end{cases}
\]
4.3 Research Objective 2

Let $A$ be the $m \times n$ constraint matrix of an ILP in the form of ILP (2.14) and $b$ be the right hand side. Let $G(A, 0, c, d)^{LP}$ be the automorphism group of $P_A = A^T (A A^T)^+ A$ that preserves $c$ and $d$. Let $B = \{e_1, e_2, \cdots, e_n\}$ be the standard orthonormal basis of $\mathbb{R}^n$ and $O_1, O_2, \cdots, O_r$ be the orbits of $G(A, 0, c, d)^{LP}$ in $B$. The fixed subspace of $\mathbb{R}^n$ under the action of $G(A, 0, c, d)^{LP}$ is defined as

$$\text{Fix}_{G(A, 0, c, d)^{LP}}(\mathbb{R}^n) := \{x \in \mathbb{R}^n | \gamma x = x \text{ for all } \gamma \in G(A, 0, c, d)^{LP}\}.$$

Lemma 3 in Bödi et al. [4] implies that

$$\text{Fix}_{G(A, 0, c, d)^{LP}}(\mathbb{R}^n) = \text{Span} (\beta(O_1), \beta(O_2), \cdots, \beta(O_r)),$$

where $\beta(S) = (\sum_{v \in S} v)/|S|$. Let the rows of $E$ be a basis for $\text{Span} (\beta(O_1), \beta(O_2), \cdots, \beta(O_r))^\perp$. If the LP relaxation set intersected with the fixed space,

$$T_{\text{Fix}_{G(A, 0, c, d)^{LP}}}^{LP} = \{x \in \mathbb{Z}^n_{\geq 0} | Ex = 0 \text{ and } x \text{ satisfies equations (2.14)}\},$$

is non-empty then $G(A, 0, c, d)^{LP} = G(A, b, c, d)^{LP}$. This follows from the argument in the beginning of Section 4.2.

On the other hand, if $T_{\text{Fix}_{G(A, 0, c, d)^{LP}}}^{LP}(\mathbb{R}^n)$ is empty, one must have $G(A, b, c, d) \subseteq G(A, 0, c, d)^{LP} \subsetneq G(A, b, c, d)^{LP}$, where $G(A, b, c, d)$ is defined as in Section 2.4. To find $G(A, b, c, d)^{LP}$ in this case, let

$$G(A, 0, c, d)^{LP} = \bigcup_{i=1}^{\rho} G(A, b, c, d)g_i G(A, b, c, d)$$

be the double coset decomposition of $G(A, 0, c, d)^{LP}$ using the subgroup $G(A, b, c, d)$. Then, as discussed in Bremner et al. [5], either $(G(A, b, c, d)g_i G(A, b, c, d)) \cap G(A, b, c, d)^{LP} = \emptyset$ or $G(A, b, c, d)g_i G(A, b, c, d) \subset G(A, b, c, d)^{LP}$. Let $G_{\text{ext}} = \langle g_1, G(A, b, c, d) \rangle$ be the group generated by $g_1$ and $G(A, b, c, d)$. Calculate $\text{Fix}_{G_{\text{ext}}}^{LP}(\mathbb{R}^n)$ and $T_{\text{Fix}_{G_{\text{ext}}}^{LP}}^{LP}$, as described in the previous paragraph, by replacing $G(A, 0, c, d)^{LP}$ with $G_{\text{ext}}$. If $T_{\text{Fix}_{G_{\text{ext}}}^{LP}}^{LP}$ is non-empty update
\( G(A, b, c, d) \) with \( G_{\text{ext}} \). Repeat the same procedure with \( G_{\text{ext}} = \langle g_i, G(A, b, c, d) \rangle \) for \( i = 2, \cdots, p \). The resulting \( G(A, b, c, d) \) in the end is equal to \( G(A, b, c, d)^{\text{LP}} \).

This method was first tested on the OA(\( N, k, s, t \)) cases listed in Table 4.1 by using both the constraints (2.2) with a 0 objective function as well as using ILP (2.4). As expected, this method found \( G(A, 0, c, d)^{\text{LP}} = G(A, b, c, d)^{\text{LP}} \) in all cases. To further test this method, a number of library MILPs featured in Liberti [18] were studied. Each inequality constraint was converted to an equality constraint by adding a slack variable. Each added slack variable was labeled to be to be an integer variable if the integrality of the variable could be deduced from the constraint to which it was added. The results of that study are listed in Table 4.2. The \( G(A, b, c, d) \) groups sizes found are the same as those found by Liberti [18]. The code used to generate this table is found in Section B.6.

| timtab2  | 256             | 2               | 2               | 265             | 628             | 20.8            |

In this set of problems, $G(A, b, c, d)^{\mathrm{LP}}$ is either $G(A, 0, c, d)^{\mathrm{LP}}$ or $G(A, b, c, d)$, with $G(A, b, c, d)^{\mathrm{LP}} = G(A, 0, c, d)^{\mathrm{LP}}$ in most of the cases. In many of these cases, $|G(A, b, c, d)^{\mathrm{LP}}| > |G(A, b, c, d)|$. Hence, this theory reveals hidden symmetries that could not otherwise be detected. If a mixed integer solver with isomorphism pruning is used on these problems, it is expected that exploiting the larger groups would overcome the computational burden of added slack variables to convert all constraints to equalities.

This method can also be applied to solve ILP (2.10). However, this requires adding $n^2 - 1$ binary slack variables. This increases the total number of binary variables in ILP (2.10) to $(3n + 11)(n - 1)/2$. Holzmann et al. [15] found all nonequivalent Williamson matrices up to order $n = 59$. The next open case is $n = 61$, which would require solving an ILP with 5,820 variables. The computer used for this research was unable to find $G(A(12, 2, 2), 0)^{\mathrm{LP}}$ for ILP (2.4), which is an ILP with 4,096 variables. Therefore, the first open case, $n = 61$, is beyond the reach of the current available resources. The
nonlinear form of this ILP has only 240 variables and it may be possible to solve that version. However, binary nonlinear programming is beyond the scope of this dissertation.

4.4 Research Objective 3

For fixed $k, s$ and $t$, the number of non-isomorphic OA($\lambda s', k, s, t$) grows exponentially with $\lambda$; see Bulutoglu and Margot [7] and Bulutoglu and Ryan [8]. This makes it impossible to enumerate all non-isomorphic OA($\lambda s', k, s, t$) for $k$ close to $k_{\text{max}}(N, s, t)$ and large $\lambda$ using any of the extension algorithms of Bulutoglu and Ryan [8], since these algorithms require finding all non-isomorphic OA($\lambda s', i, s, t$) for $i \leq k$. On the other hand, all non-isomorphic OA($\lambda s', k, s, t$) can be enumerated by solving ILP (2.4) with the Margot [22] Branch-and-Cut algorithm with isomorphism pruning using group $G(A(k, s, t), \lambda 1)^{\text{LP}}$. However, this approach also fails for $k \geq 12$ or large $\lambda$, as it suffers from the exponential growth of the Branch-and-Cut enumeration tree with $k$ and $\lambda$.

If $|G(k, s, t)|/|G(A(k, s, t), \lambda 1)^{\text{LP}}|$ is large, using $G(k, s, t)$ instead of $G(A(k, s, t), \lambda 1)^{\text{LP}}$ will significantly reduce the Branch-and-Cut enumeration tree without compromising the correctness of the answer to the feasibility question of an OA($\lambda s', k, s, t$). For $i = t, t + 1, \cdots, k - 1$, a permutation $\pi^i \in G(i, s, t)$ extends to a permutation $\pi^k \in G(k, s, t)$ if and only if the action of permutation $\pi^k$ on the first $i$ factors of each of $s^k$ possible $k$ factor level combinations is identical to that of $\pi^i$. Using $G(i, s, t)$ instead of $G(A(i, s, t), \lambda 1)^{\text{LP}}$ for $i = t, t + 1, \cdots, k$ (when $|G(i, s, t)|/|G(A(i, s, t), \lambda 1)^{\text{LP}}|$ is large) will also improve the efficiency of extension algorithm in Figure 2.4 significantly by decreasing the enumeration tree sizes, the number of solutions to the ILPs to be solved and consequently the total number of ILPs to be solved. However, using $G(i, s, t)$ may cause the algorithm in Figure 2.4 to incorrectly declare an OA($\lambda s', k, s, t$) to be infeasible. The correctness of the answer to the feasibility question of an OA($\lambda s', k, s, t$) will not be compromised if and only if each permutation in $G(i, s, t)$ extends to a permutation in $G(k, s, t)$.  

53
We computed $\mathcal{G}(i,s,t)$ for $i \leq k$ for many $k,s,t$ combinations to determine $|\mathcal{G}(i,s,t)|/|\mathcal{G}(i,s,t)\mathcal{A}(i,s,t),\lambda^1|^{LP}$. This was accomplished as follows:

1. Find the indicator vectors of all OA($\lambda s', i, s, t$) either by finding all solutions to ILP (2.4) or by generating them from a set of all non-isomorphic OA($\lambda s', i, s, t$).

2. Let $\mathbf{M}$ be a $n \times s'$ matrix whose rows are the indicator vectors of all OA($\lambda s', i, s, t$), where $n$ is the number of all OA($\lambda s', i, s, t$).

3. Compute $G(\mathbf{M}, 1, 1, 1) = \mathcal{G}(i, s, t)$ by computing the automorphism group of a vertex colored bipartite graph (the same way $G(\mathbf{A}, 1, 1, 1)$ in equation (2.15) is computed by Margot [23]). If $\mathbf{M}$ is not a binary matrix, then an edge colored vertex colored bipartite graph, where each color represents a distinct value in $\mathbf{M}$, must be used. Edge coloring of such a graph was implemented as described in the Nauty software documentation [25].

For many non-trivial OA($\lambda s', i, s, t$) cases, $\mathbf{M}$ is huge. Hence, for such cases Step 3 is disk space intensive. The following theorem provides a more efficient way of determining $\mathcal{G}(i, s, t)$ by converting this problem to finding the automorphism group of $\mathbf{B}^T (\mathbf{B}\mathbf{B}^T)^+ \mathbf{B}$, where $\mathbf{B}$ is a basis of the row space of $\mathbf{M} - \frac{1}{s'} \mathbf{J}_n^s$. Then the automorphism group of $\mathbf{P}_{\mathbf{B}^T} = \mathbf{B}^T (\mathbf{B}\mathbf{B}^T)^+ \mathbf{B}$, $G_{\mathbf{P}_{\mathbf{B}^T}}$ is equal to $\mathcal{G}(i, s, t)$.

**Theorem 13.** Let $\mathbf{M}$ be the $n \times s'$ matrix above. Let the rows of $\mathbf{B}$ be a basis for the row space of $\mathbf{M} - \frac{1}{s'} \mathbf{J}_n^s$. Then the automorphism group of $\mathbf{P}_{\mathbf{B}^T} = \mathbf{B}^T (\mathbf{B}\mathbf{B}^T)^+ \mathbf{B}$, $G_{\mathbf{P}_{\mathbf{B}^T}}$ is equal to $\mathcal{G}(i, s, t)$.

**Proof.** By the argument in Section 4.2, the automorphism group of $\mathbf{P}_{\mathbf{B}^T}$ is the set of all permutations in $S_{s'}$ that preserve $R\left((\mathbf{M} - \frac{1}{s'} \mathbf{J}_n^s)^T\right)$, the row space of $\mathbf{M} - \frac{1}{s'} \mathbf{J}_n^s$. Clearly, $R\left((\mathbf{M} - \frac{1}{s'} \mathbf{J}_n^s)^T\right)$ is a subspace of $\text{Null}(\mathbf{A}(k,s,t))$. Every solution to ILP (2.4) has the form $\mathbf{x} = \mathbf{v} + \frac{1}{s'} \mathbf{1}_{s'}$ for some $\mathbf{v} \in R\left((\mathbf{M} - \frac{1}{s'} \mathbf{J}_n^s)^T\right) \subseteq \text{Null}(\mathbf{A}(k,s,t))$. For $g \in G(i,s,t)$, $\mathbf{x} = \mathbf{v} + \frac{1}{s'} \mathbf{1}_{s'}$ and $g\mathbf{x} = g\mathbf{v} + \frac{1}{s'} \mathbf{1}_{s'}$ both solve ILP (2.4). Hence, $g\mathbf{v} \in R\left((\mathbf{M} - \frac{1}{s'} \mathbf{J}_n^s)^T\right)$ and
\( G(i, s, t) \subseteq G_{P_{B^T}} \). Furthermore, \( g \mathbf{x} = g \mathbf{y} + \frac{1}{s^k} \mathbf{1}_{s^k} \) also solves ILP (2.4) for \( g \in G_{P_{B^T}} \). Hence,
\[ G_{P_{B^T}} \subseteq G(i, s, t). \]

The entries in Table 4.3 were computed as follows:

1. Compute a basis \( \mathbf{B} \) for the row space of \( (\mathbf{M} - \frac{1}{s^k} \mathbf{J}_{s^k}) \) via successive applications of Q-R decomposition, taking 100 vectors at a time. Report \( \text{rank}(\mathbf{M} - \frac{1}{s^k} \mathbf{J}_{s^k}) = \text{rank}(\mathbf{B}). \)

2. Calculate \( P_{B^T} = \mathbf{B}^T (\mathbf{B}\mathbf{B}^T)^+ \mathbf{B}. \)

3. Convert \( P_{B^T} \) to an edge colored graph with \( s^k \) vertices as described in Section 4.2.

4. Use Nauty [25] to find the automorphism group of the graph.

The following theorem connects the Table 4.3 results to a conjecture on \( \text{OA}(s', k, s, t) \):

**Theorem 14.** Let \( k = i \) and assume that an \( \text{OA}(\lambda s', k, s, t) \) exists. Let \( \text{Conv}(\mathbf{M}) \) be the convex hull of the rows of \( \mathbf{M} \). Then, \( \text{rank}(\mathbf{B}) = \dim(\text{Conv}(\mathbf{M})). \)

**Proof.** Let \( \mathcal{B} = \{ e_x \mid x \in \mathbf{D}_{s^k} \} \) be the standard orthonormal basis for \( \mathbb{R}^{s^k} \) indexed with the full factorial design \( \mathbf{D}_{s^k} \). Let \( G_{s^k} = G(\mathbf{A}, \lambda \mathbf{1}) = S_{\{1,2,\ldots,s\}} \wr S_k \) act on elements of \( \mathcal{B} \) by \( e_x \xrightarrow{g} e_{gx} \) for each \( g \in S_{\{1,2,\ldots,s\}} \wr S_k \). Let \( O \) be the orbit of \( e_1 \). As the action of \( S_{\{1,2,\ldots,s\}} \wr S_k \) on \( \mathcal{B} \) is transitive, each element in \( \mathcal{B} \) appears in \( O \). Then, \( \beta(O) = s^{-k} \mathbf{1}_{s^k} \), where \( \beta(O) \) is defined as in Section 4.3. Hence, by Lemma 3 in Bödi et al. [4],

\[ \text{Fix}_{G(\mathbf{A}, \lambda \mathbf{1})}(\mathbb{R}^{s^k}) = \text{Span}(\mathbf{1}_{s^k}). \]

Now, let \( \mathbf{y}^{T}_{1 \times s^k} \) be a row of \( \mathbf{M} \). Then, \( \beta(\mathbf{y}) = \alpha \mathbf{1}_{s^k} \) for some \( \alpha \in \mathbb{R} \) as \( \beta \) is the projection operator onto \( \text{Fix}_{G(\mathbf{A}, \lambda \mathbf{1})}(\mathbb{R}^{s^k}) \). For \( \mathbf{y} \in \mathbb{R}^{s^k}, S_{\{1,2,\ldots,s\}} \wr S_k \) acts on coordinates \( y_x \) of \( \mathbf{y} \) by \( y_x \xrightarrow{g} y_{gx^{-1}(x)} \). Let \( O_y \) be the orbit of \( \mathbf{y} \) under this action. Then,

\[ \beta(\mathbf{y}) = \sum_{v \in O_y} \frac{\mathbf{y}}{|O_y|} = \alpha \mathbf{1}_{s^k}. \]
Each $v$ satisfies the equality constraints in ILP (2.4). Then, $\sum_{v \in O_y} \frac{v}{|O_y|} = \alpha 1_{x_y}$ also satisfies the same constraints. This forces $\alpha = \lambda / s^k$. Hence, $(\lambda / s^k 1_{x_y})$ is in $\text{Conv}(M)$. Then, $\text{rank}(B) = \text{rank} \left( M - \frac{1}{s^k} J_n \right) = \dim(\text{Conv}(M))$. \qed

The second column of Table 4.3 is the size of the automorphism group, the third indicates if $|G(i, s, t)| = |G(A(i, s, t), , \lambda 1)^{LP}|$, the fourth is the number of rows in $B^T \left( = s^i \right)$, the fifth is the upper bound on the rank of $B \left( = \sum_{j=i+1}^{i} \binom{i}{j} (s - 1)^j \right)$, the sixth is the rank of $B$, and the seventh column is the minimum difference between two entries in $P_{B^T}$. The code used to compute this table is found in Section B.3.

Table 4.3: $G(i, s, t)$ and rank($B$)

UB(rank($B$)) is the dimension of the affine space to which each indicator vector of the $OA(\lambda s^i, i, s, t)$ belongs. For $OA(s^i, i, s, t)$, Appa et al. [1] conjectured that $UB($rank($B$)) =
\( \dim(\text{Conv}(M)) \), where \( \text{Conv}(M) \) is the convex hull of the rows of \( M \). By Theorem 14, 
\( \text{rank}(B) = \dim(\text{Conv}(M)) \). Hence, Table 4.3 appears to invalidate this conjecture for general \( \text{OA}(\lambda s^t, i, s, t) \). However, there may be inaccuracies in the reported \( \text{rank}(B) \) values since not all solutions may have been enumerated by the solver or performing Q-R decomposition with 100 vectors at a time may have introduced numerical precision errors that lead to rejecting linearly independent rows of \( (M - \frac{1}{x^e}J_n^t) \) from \( B \). If \( B \) is not a basis for \( (M - \frac{1}{x^e}J_n^t) \), the calculation of \( G(i, s, t) \) would be incorrect. Hence, it is essential to make sure that the elements in column 6 are calculated correctly. For smaller cases, in which errors are less likely, Table 4.3 not only verifies the Appa \textit{et al.} [1] conjecture, but also suggests that \( G(i, s, t) = G(A(i, s, t, \lambda I)) \).

4.5 Research Objective 4

Let \( A_{\text{eq}} \) and \( b_{\text{eq}} \) be the constraint matrix and the corresponding right hand side of the equality constraints in ILP (2.13). Let \( G(A_{\text{eq}}, 0) \) and \( G(A_{\text{eq}}, b_{\text{eq}}) \) be computed as described in Sections 4.2 and 4.3 respectively. Let \( H_{\text{eq}1}^{\text{LP}} \) and \( H_{\text{eq}2}^{\text{LP}} \) be the maximal subgroups of \( G(A_{\text{eq}}, 0)^{\text{LP}} \) and \( G(A_{\text{eq}}, b_{\text{eq}})^{\text{LP}} \) that map the input \( \text{OA}(\lambda s^t, k - 1, s, t) \) to itself.

**Theorem 15.** \( H_{\text{eq}1}^{\text{LP}} = H_{\text{eq}2}^{\text{LP}} \).

**Proof.** Since \( G(A_{\text{eq}}, b_{\text{eq}})^{\text{LP}} \subseteq G(A_{\text{eq}}, 0)^{\text{LP}} \), then \( H_{\text{eq}2}^{\text{LP}} \subseteq H_{\text{eq}1}^{\text{LP}} \). Let \( \hat{x} \) be such that 
\[
\hat{x}_{il-1} + j = \frac{r_{il}}{s}
\]
where \( j = 1, 2, \ldots, s - 1 \), and \( i_l \) be as in the modified ILP (2.13). Then, \( \hat{x} \) is a fractional solution to the modified ILP (2.13). Hence, every solution to the LP relaxation of the modified ILP (2.13) can be written in the form 
\[
p_{\text{max}} \mathbf{1} \geq x = \hat{x} + v \geq 0
\]
for some \( v \) such that \( -\hat{x} \leq v \leq p_{\text{max}} \mathbf{1} - \hat{x} \) and \( v \in \text{Null}(A_{\text{eq}}) \). This is true because \( \hat{x} \) is a particular solution to \( A_{\text{eq}}x = b_{\text{eq}} \) and \( x \geq 0 \). Now, the set of all permutations
of variables that map the input $O\!A(\lambda s', k-1, s, t)$ to itself must map $\hat{x}$ to itself. Then,
\[ G(A_{eq}, b_{eq})^{LP} \cap H_{eq}^{LP} = G(A_{eq}, 0)^{LP} \cap H_{eq}^{LP}. \]
Thus, $H_{eq}^{LP} = H_{eq}^{LP}$. \hfill $\Box$

Add back the variables $\{x_{(i-1)s+l}\}_{i=1}^{h}$ to ILP (2.13), and replace $\sum_{l=1}^{s-1} x_{(i-1)s+l} \leq r_{ij}$ with $\sum_{l=1}^{s} x_{(i-1)s+l} = r_{ij}$. Also, add the constraints $\sum_{l=1}^{h} x_{(i-1)s+l} = \lambda s'^{-1}$ and
\[ \sum_{l=1}^{h} d'_{p,a_{1}}d'_{p,a_{2}}\cdots d'_{p,a_{q-1}}x_{(i-1)s+q} = \lambda s'^{-q}. \]
Let $A_{all}$ be the resulting matrix whose rows correspond to the equality constraints in the modified ILP (2.13), and $b_{all}$ be the corresponding right hand side. Let $G(A_{all}, 0)^{LP}$ and $G(A_{all}, b_{all})^{LP}$ be computed as described in Sections 4.2 and 4.3 respectively. Let $H_{all_1}^{LP}$ and $H_{all_2}^{LP}$ be the maximal subgroups of $G(A_{all}, 0)^{LP}$ and $G(A_{all}, b_{all})^{LP}$ that map the input $O\!A(\lambda s', k-1, s, t)$ to itself.

**Theorem 16.** $H_{all_1}^{LP} = H_{all_2}^{LP}$.

The proof is skipped as it is analogous to the proof of Theorem 15.

Let $H_{s,k}$ be the maximal subgroup of $G(A(k, s, t), \lambda 1)$ (as defined in Section 2.4) that maps the input $O\!A(\lambda s', k-1, s, t)$ to itself and preserves $\{x_{(i-1)s+l} : l = 1, 2, \cdots, h\}$. Let $H_{s,k}^{LP}$ be the maximal subgroup of $G(A(k, s, t), \lambda 1)^{LP}$ from Section 4.2 that maps the input $O\!A(\lambda s', k-1, s, t)$ to itself and preserves $\{x_{(i-1)s+l} : l = 1, 2, \cdots, h\}$. When $H_{s,k}^{LP}$ or $H_{all_1}^{LP}$ is used, some OD classes of $O\!A(\lambda s', k, s, t)$ may be lost. However, at least one $O\!A(\lambda s', k, s, t)$ will be found if the input $O\!A(\lambda s', k-1, s, t)$ can be extended to an $O\!A(\lambda s', k, s, t)$.

The Figure 2.6 algorithm was used to enumerate all non-OD equivalent OD(160, k, 2, 4) for $k \leq k_{\text{max}}(160, 2, 4)$ by solving ILPs (2.13) and modified ILPs (2.13). The modified ILPs (2.13) were solved using $H_{all_1}^{LP}$ and $H_{s,k}^{LP}$. $H_{s,k}$ and $H_{eq}^{LP}$ were used to solve the original ILPs (2.13). Comparisons were made for efficiency. Only using $H_{s,k}$ or $H_{eq}^{LP}$ guarantee that no OD classes are lost. However, a comparison of the found number of non-OD equivalent OAs to those found using $H_{s,k}$ shows that none of the methods lost OD classes of OAs. At the end of each extension step, right before the Nauty [25] reduction, using $H_{s,k}$ and $H_{eq}^{LP}$ produced the exact same number of solutions. In three of the extensions to $k = 8$, $H_{eq}^{LP}$ was in the order of $10^{35}$. These extensions were the only infeasibles. For the remaining feasible
extensions, $|H_{LP}^{eq1}| = |H_{s,k}|$. Also, for each extension to $k = 9, 10$, $|H_{LP}^{eq1}| = |H_{s,k}|$. Hence, using $H_{LP}^{eq1}$ was slightly slower than using $H_{s,k}$ as it requires calculating the projection matrix $P_{A_{eq}}$ for each extension. In the extensions to $k = 11$, $|H_{LP}^{eq1}| = |H_{s,k}|$ in all but four of the extensions. In those four extensions, $|H_{LP}^{eq1}|$ is much larger than $|H_{s,k}|$. This explains why using $H_{LP}^{eq1}$ was about seven times faster than using $H_{s,k}$ in the extension to $k = 11$. However, using $H_{s,k}$ was still slightly faster for the whole $OA(160, k, 2, 4)$ enumeration starting at $k = 7$.

Using $H_{s,k}^{LP}$ and $H_{all1}^{LP}$ resulted in similar solution times. Using $H_{all1}^{LP}$ outperformed $H_{s,k}$ for extensions up to eight factors. However, $H_{s,k}$ was much faster than $H_{all1}^{LP}$ for the extension from eight factors to nine factors. Since this is the bottleneck extension, overall, using $H_{s,k}$ was faster than using $H_{all1}^{LP}$ or $H_{s,k}^{LP}$. The number of non-OD equivalent OAs found by each extension method and their respective run times are listed in Table 4.4.

$OA(176, k, 2, 4)$ enumerations were also made to assess the speed of solving modified ILPs (2.13) with $H_{all1}^{LP}$. The same sequence of enumerations will be implemented by solving ILPs (2.13) with $H_{s,k}$. The increasing computational time in solving modified ILPs (2.13) with $H_{all1}^{LP}$ for the $OA(176, k, 2, 4)$ cases suggests that the $OA(192, k, 2, 4)$ cases are out of computational reach even if ILPs (2.13) are solved with $H_{s,k}$.

The code to compute $H_{s,k}$ is found in Bulutoglu and Ryan [8]. The modification to the Bulutoglu and Ryan [8] code to make it use $H_{s,k}^{LP}$ is found in Section B.4. The modification to the Bulutoglu and Ryan [8] code to make it use $H_{all}^{LP}$ is found in Section B.5.
5.1 Conclusions

In Chapter 3, it was first shown that none of the inequalities in the LP relaxation of ILP (3.2) that describes OA($N, k, s, t$)s is redundant. This renders each inequality to be a facet of the LP relaxation. In Section 3.3, this result was used to explicitly show that the symmetry group $G(A'(k, s, t), b_m)^{LP}$ of the LP relaxation of ILP (3.2) is $S_{\{2,\ldots,s\}} \triangleleft S_k$. Even though it is easy to see that $S_{\{2,\ldots,s\}} \subseteq G(A'(k, s, t), b_m)^{LP}$, it is far from trivial to show that $S_{\{2,\ldots,s\}} \triangleleft S_k = G(A'(k, s, t), b_m)$. The practical value of this result is that there are no additional symmetries that can be exploited by using a subgroup of $G(A'(k, s, t), b_m)^{LP}$ to find OAs by solving ILP (3.2).

Bulutoglu and Margot [7] previously proved that $G_{s,k} = S_{\{1,\ldots,s\}} \triangleleft S_k$ is a subgroup of the automorphism group $G(A, \lambda 1_1, 1, p_{\max}1)$ of ILP (2.4). Based on computational observations, they conjectured that $G_{s,k} = G(A, \lambda 1_1, 1, p_{\max}1)$. This conjecture was proved in Chapter 3.

In Section 4.2.1, the Margot ILP solver [22] was used to find a set of all non-isomorphic solutions to ILP (3.2) exploiting $G(A(k, s, t), b_m)^{LP}$. This was compared to finding all non-isomorphic solutions to ILP (2.5), which has more variables, by exploiting the larger group $G_{s,k}$. It is legitimate to use $G_{s,k}$ to solve ILP (2.5) as ILP (2.5) and ILP (2.4) have the same feasible sets defined by the same variables. For most of the cases, a set of all non-isomorphic solutions to ILP (2.5) with the larger number of variables was found faster.

When the Margot ILP solver [22] is used to solve a symmetric ILP, it is essential to find larger subgroups of the ILP’s symmetry group to speed up the enumeration. One easy-to-compute subgroup is the automorphism group of the formulation, $G(A, b, c, d)$. This group coincides with the symmetry group of the LP relaxation $G(A, b, c, d)^{LP}$, provided that the LP relaxation has no redundant constraints and is full dimensional. Hence, given an ILP formulation whose LP relaxation is full dimensional, finding $G(A, b, c, d)^{LP}$ is a matter of...
culling the redundant constraints and computing the automorphism group of the resulting formulation. On the other hand, for an ILP whose LP relaxation is not full dimensional, the LP relaxation may contain hidden symmetries not captured by $G(\mathbf{A}, \mathbf{b}, \mathbf{c}, \mathbf{d})$, even after removing all the redundant constraints.

The LP relaxation symmetry group always contains the automorphism group of an ILP formulation. Thus, it is more desirable to exploit the LP relaxation symmetry group. The LP relaxation of an ILP with equality constraints is not full dimensional. Hence, it is possible that the LP relaxation symmetry group of such an ILP strictly contains the ILP formulation automorphism group. In Sections 4.2 and 4.3, an algorithm was developed for finding this potentially larger group. This is the first algorithm for this purpose in the literature.

In Section 4.2, a special case of the developed algorithm is applied to LP relaxations of ILPs with equality constraints that describe orthogonal arrays. Computational results not only revealed previously unknown hidden symmetries of the ILP (2.5) formulation of the OA problem, but also demonstrated that exploiting the newly found symmetries decreases solution times significantly. In Section 4.2.2, these newly found hidden symmetries were explicitly described as the automorphism group $G_{k,t}^J$ of a system of equations derived from equations (4.4). Furthermore, for each $k, t$ combination, $G_{k,t}^I$ was conjectured to be the same as the symmetry group of the LP relaxation of ILP (2.5).

In Section 4.3, the newly developed algorithm was used to find the LP relaxation symmetry groups of modified versions of MILPs featured in Liberti [18]. All inequalities in each MILP were first converted to equality constraints by adding slack variables. In many of these cases, $|G(\mathbf{A}, \mathbf{b}, \mathbf{c}, \mathbf{d})_{\text{LP}}| > |G(\mathbf{A}, \mathbf{b}, \mathbf{c}, \mathbf{d})|$. Hence, this algorithm reveals hidden symmetries that do not exist in $G(\mathbf{A}, \mathbf{b}, \mathbf{c}, \mathbf{d})$. If a MILP solver with isomorphism pruning is used on these problems, it is expected that exploiting
the larger groups would overcome the additional computational burden due to the added slack variables.

In Section 4.4, $G(k, s, t)$, the symmetry group of ILP (2.5), was calculated for several $k, s, t$ combinations. For most cases, all the symmetry in the OA problem was captured by the symmetry group of its LP relaxation. Differences between these groups occurred in larger cases where numerical precision errors were more likely to throw off calculations. As a side benefit, the method developed for calculating $G(k, s, t)$ also checked the validity of a conjecture made by Appa et al. [1]. The fact that this conjecture was verified only in the smaller cases suggests that this method suffers from numerical precision errors for the larger cases.

In Section 4.5, the LP relaxation symmetry group was used in various ways for each of the OA extensions based on ILPs (2.13) in the Bulutoglu and Ryan [8] OA extension algorithm. Even though there were some extensions in which larger groups were found, the computational savings did not make up for the time lost finding these groups. The OA extension algorithm developed by Bulutoglu and Ryan [8] still remains the fastest known for enumerating all non-isomorphic OA(160, k, 2, 4) and OA(176, k, 2, 4).

In the next section, some open problems are presented that arose from the research in this dissertation. In Section 5.3, a set of conjectures is provided based on observations from the computational research in Chapter 4. It is proposed that future research efforts resolve these conjectures by either proving them or finding counterexamples. In Section 5.4, a list of computational projects is proposed to improve upon the computational research in Chapter 4.

5.2 Open Problems

Problem 1. Determine the isomorphism class of the group $G(A(k, s, t), \lambda_1)^{LP}$ in Section 4.1 by determining how it relates to its subgroup $G(A(k, s, t), \lambda_1) = S_{\{1,2,\ldots,s\}} \wr S_k$.

Problem 2. Develop the theory and computational tools in this dissertation for $t$-designs.
5.3 Conjectures

Conjecture 2. If an $OA(\lambda s', i, s, t)$ exists, then $\dim(Conv(M)) = \sum_{j=t+1}^{i} \binom{i}{j} (s - 1)^j$, where $M$ is as in Section 4.4.

Conjecture 3. If an $OA(\lambda s', i, s, t)$ exists, then $G(i, s, t) = G(A(i, s, t), \lambda 1)^{LP}$, where $G(A(i, s, t), \lambda 1)^{LP}$ is as in Section 4.2 and $G(i, s, t)$ is as in Section 4.4.

Conjecture 4. Let $G(A(k, s, t), \lambda 1)^{LP}$ be as in Section 4.1. Then,

$$|G(A(k, s, t), \lambda 1)^{LP}| = \begin{cases} 
(k + 1)! 2^k & \text{if } t \text{ is even, } s = 2, \text{ and } 1 \leq t < k, \\
k!(s!)^k & \text{if } (t \text{ is odd or } s > 2) \text{ and } 1 \leq t < k, \\
s^k! & \text{otherwise.}
\end{cases}$$

To prove this conjecture, let $E(N, k, t)$ be the constraint matrix of the system of equations (4.4). Now, let $P_{E(N,k,t)^T}$ be the projection matrix onto the row space of $E(N, k, t)$. Then, as the rows of $E(N, k, t)$ are orthogonal, $P_{E(N,k,t)^T} = \frac{1}{N} E(N, k, t)^T E(N, k, t)$. Furthermore, $G(A(k, 2, t), \lambda 1)^{LP}$ is the automorphism group of this matrix. After fixing an order for the variables, come up with a closed form formula for $P_{E(N,k,t)^T}$. Use this formula to calculate the automorphism group.

Conjecture 5. Let $A_{all}$, $b_{all}$, and $H_{s,k}^{LP}$ be as in Section 4.5. Let $\hat{A}_{all}$ and $\hat{b}_{all}$ be obtained from $A_{all}$ and $b_{all}$ by deleting the constraints $\sum_{j=1}^{s} x_{(i-1)s+j} = r_i$. Let $G(\hat{A}_{all}, 0)^{LP}$ and $G(\hat{A}_{all}, \hat{b}_{all})^{LP}$ be computed as described in Sections 4.2 and 4.3, respectively. Let $\hat{H}^{LP}_{all_1}$ and $\hat{H}^{LP}_{all_2}$ be the maximal subgroups of $G(\hat{A}_{all}, 0)^{LP}$ and $G(\hat{A}_{all}, \hat{b}_{all})^{LP}$ that map the input $OA(\lambda s', k - 1, s, t)$ to itself. Then, $\hat{H}^{LP}_{all_1} = \hat{H}^{LP}_{all_2} = H_{s,k}^{LP}$.

5.4 Computational Research Improvements

Project 1. Resolve the numerical precision issues in the methods and algorithms used to develop Table 4.3.
Project 2. If Conjecture 5 is proven, compute $\hat{H}_{\text{all}}^{LP}$ by calculating the singular value decomposition of $\hat{A}_{\text{all}}$ as described in Section 4.2 for all of the algorithms in this dissertation that require $H_{s,k}^{LP}$.

Vita

Major Andrew J. Geyer graduated from Minot High School in Minot, North Dakota in May 1996. He entered undergraduate studies at North Dakota State University in Fargo, North Dakota where he graduated with a Bachelor of Science degree in Physics in May 2000. He was commissioned through Detachment 610, AFROTC at North Dakota State University.

His first assignment was to the Air Force Institute of Technology’s Basic Meteorology Program at Texas A&M University in College Station, Texas. In September 2001, Maj Geyer was assigned to the 18th Weather Squadron at Fort Bragg, NC, where he served combat tours in Operations Enduring Freedom and Iraqi Freedom as a Combat Weather Team leader attached to the U.S. Army’s 82nd Airborne Division. In May 2004, Maj Geyer reported to Kunsan Air Base, Republic of Korea, where he served as the weather flight commander for the 8th Fighter Wing. In July 2005, he reported to Fort Benning, Georgia where he served as Commander, Detachment 4, 10th Combat Weather Squadron and as the Staff Weather Officer for the U.S. Army’s 75th Ranger Regiment. During that assignment, Maj Geyer deployed as the Joint METOC Officer assigned to Combined Joint Special Operations Task Force-Arabian Peninsula in Iraq. In August 2007, he entered the Graduate School of Engineering and Management, Air Force Institute of Technology where he received a Master of Science in Operations Research. In 2009, he was assigned to Headquarters, Air Force Weather Agency at Offutt Air Force Base, Nebraska. In 2010, he served as the Senior Meteorology Officer for the International Security Assistance Force in Kabul, Afghanistan. In 2011, Maj Geyer returned to the Graduate School of Engineering and Management, Air Force Institute of Technology where he pursued a Doctor of Philosophy in Applied Mathematics - Statistics.
**Title:** Different Formulations of the Orthogonal Array Problem and Their Symmetries

**Abstract:**  
Modern statistical experiments routinely feature a large number of input variables that can each be set to a variety of different levels. In these experiments, output response changes as a result of changes in the individual factor level settings. Often, an individual experimental run can be costly in time, money or both. Therefore, experimenters generally want to gain the desired information on factor effects from the smallest possible number of experimental runs. Orthogonal arrays provide the most desirable designs. However, finding orthogonal arrays is a very challenging problem. There are numerous integer linear programming formulations (ILP) in the literature whose solutions are orthogonal arrays. Because of the nature of orthogonal arrays, these ILP formulations contain symmetries where some portion of the variables in the formulation can be swapped without changing the ILP. These symmetries make it possible to eliminate large numbers of infeasible or equivalent solutions quickly, thereby greatly reducing the time required to find all non-equivalent solutions to the ILPs.  

In this dissertation, a new method for identifying symmetries is developed and tested using several existing and new ILP formulations for enumerating orthogonal arrays.
