Abstract

Hierarchical Linear Models (HLMs), also known as multi-level models, are an extension of multiple regression analysis and can aid in the understanding of human and machine workloads of a system. These models allow for prediction and testing in systems with hierarchies of two or more levels. The complex interrelated variability of these multi-level models exists in operational settings, such as the Air Force Distributed Common Ground System Full Motion Video (AF DCGS FMV) community which is composed of individuals (Level-1), groups (Level-2), units (Level-3), and organizations (Level-4). Through the development of sample size requirements and considerations for multi-level models, this research determined necessary requirements and strategies to assess human-machine system performance based requests for statistical testing and evaluation. This research compares sample size recommendations to previous Level-2 HLM recommendations and extends recommendations to Level-3 and Level-4 HLMs based on varying effect sizes, level predictor variance, and error variance scenarios. Depending on the application, results demonstrate that sample size requirements may be smaller than what literature previously reported. Further, when sample size requirements cannot be met, this research develops and assesses re-sampling methods as a means to augment small samples for estimation. The operational community, DCGS FMV, has a small population of 1,000 and limited access to analysts. This research provides distributions based on Subject Matter Expert (SME) opinion for re-sampling methods to the DCGS FMV Level-3 and Level-4 HLMs. These findings provide a foundation on which sample size recommendations and extrapolation techniques for HLM are made. Such recommendations and techniques with SME input provide simulation based HLM assessments that can give initial recommendations with limited associated cost, analyst and researcher time,

and resources. These are initial steps towards advancing the Air Force's capabilities and mission understanding for human-machine based systems.

To my husband and children.

You are my world and I love you with all heart.

Acknowledgements

I would like to thank Dr. Schubert Kabban for her constant guidance and support during this endeavor. Her mentorship gave me the confidence and expertise to learn and become a better researcher and person. Also, I would like to thank my committee, Dr. Hill and Dr. White, for guiding my research and encouraging my goals during my graduate education.

I would also like to thank the 711^{th} Human Performance Wing, Human Analyst Augmentation Branch (711HPW/RHXM) for their financial support and leadership during this process. Specifically, I would like to thank Dr. Grant Erdmann for his expertise and encouraging interactions.

Lastly, I would like to thank my family and friends for their countless hours of encouragement and support both emotionally and physically. Without this I could not have worked, completed school, and raised a family.

SAMPLE SIZE REQUIREMENTS AND CONSIDERATIONS FOR MODELS TO ASSESS HUMAN-MACHINE SYSTEM PERFORMANCE

I. Introduction

The objective of this research is to aid in the understanding of the human and machine workloads of a system through the development of sample size requirements and considerations for multi-level models assessing human-machine system performance. These requirements are necessary to appropriately model and estimate the overall performance of human-machine systems of organizations at four different levels (e.g. individual, group, unit and organization). These four levels modeled simultaneously, are known as a Level-4 model and will be assessed using Hierarchical Linear Models (HLMs).

HLMs are an extension of multiple regression analysis and can analyze the complex variability inherent in the multiple levels of organizational structures simultaneously, accounting for variability both within and between levels. Within organizational studies, the response of interest (system performance) is associated to the individuals and the group to which they belong.

The complex interrelated variability of the Level-4 model exists in many settings including the small population of the Air Force Distributed Common Ground System (AF DCGS) community, which consists of approximately 6,000 analysts total. This research focuses on the Full Motion Video (FMV) analysts, a subset of the AF DCGS community. FMV analysts are a small population od less than 1,000 analysts, even a census of data may not provide enough information to adequately estimate all the parameters within the Level-4 model depending on the phenomenon. Sample size

recommendations and augmentations for a Level-4 model is paramount in the design and analysis of an appropriate study, however such guidelines do not exist.

1.1 Research Objectives

To model and evaluate a Level-4 HLM, such as for the AF DCGS FMV human-machine system's performance, the data requirements and collection for the design and implementation must first be determined. These requirements are addressed by three primary objectives, which are:

Research Objective 1. Determine the sample size requirements for up to a Level-4 Hierarchical Linear Model (HLM).

Organizational structures of interest in this research may be modeled with 2-, 3-, or 4- levels. Although some recommendations exist for Level-2 HLMs, they are mostly computationally estimated. This research derives the formulas to create sample size criteria under a variety of scenarios for Level-2, Level-3 and Level-4 HLMs. Results for Level-2 HLMs are compared to some existing literature and both Level-3 and Level-4 HLM results add to the non-existing literature.

In order to accomplish the first primary objective, this research assesses a Level-4 model under the standard assumption of normally distributed responses. Under various model conditions at all levels, the sample size requirements for each level of the Level-4 model is determined and based upon criteria of adequate power for parameter estimation.

Research Objective 2. Develop and assess re-sampling based methods as a means to augment small samples for estimation in Level-2 and Level-3 HLMs.

When sample size criteria is not met, it is plausible that the existing data may be augmented to generate a sample large enough for estimation. Assessment of a re-sampling method will be accomplished by determining the effects of distribution

misspecification as a byproduct of the extrapolation of a small sample to meet sample size requirements. Similar to Research Objective 1, Level-2 and Level-3 recommendations will be determined. Monte Carlo simulations will be constructed to examine the effects of re-sampling on parameter estimation and model specification for each of the HLM levels considered (e.g. group and unit) and the overall system performance. Note that Level-4 HLM will be addressed through the specific application of interest to this research.

Objective 3. Demonstrate an application to the notional example of the AF DCGS community that will focus on utilizing HLM system augmentation of Research Objective 2 in order to explore the effects of autonomy on the AF DCGS community Level-3 and Level-4 HLMs. This work will utilize and extend the recommendations and criteria established in Research Objective 1 and Research Objective 2.

The AF DCGS FMV community application will incorporate known Level-4 HLM predictor data with simulated novice versus expert analyst distribution error variance terms. This will help to determine how sensitive the system is to automation-modifications when comparing novice versus expert analysts in a DCGS FMV Level-3 and Level-4 HLM.

The objectives of this research provide a foundation to develop sample size requirements and considerations in order to evaluate measures of merit with respect to the overall performance of the human and machine workload of a system across different levels of an organizational structure, especially for small populations. HLM, the statistical modeling tool and technique, is proposed as the means to develop this analysis because it can be applied to the nested organizational structures in order to quantify the interrelated effects of each level of the organization on system performance. Research Objective 1 will define appropriate sample size requirements when designing a

Level-4 HLM and the results of Research Objective 2 will provide guidance as to the usefulness of re-sampling in order to meet necessary sample size requirements for a Level-2 and Level-3 HLM. These objectives together with a Level-4 applied application will generally be used to inform the analysis for HLMs with small sample sizes, and the HLM application will describe the functionality of the AF DCGS community notional example with respect to appropriate processes of merit.

1.2 Air Force Need

The Air Force Chief Scientist's 2010 S&T Vision "Technology Horizons" identifies key science and technology focus areas needed for 2030 [5]. The need for access to military systems is vital because future operational missions will consist of longer durations, overly highly populated areas, in dynamic environments and involve communication disruptions. Therefore, improving Intelligence, Surveillance, Reconnaissance (ISR) is essential. The manpower costs and resources associated with processing, exploitation, and dissemination (PED) of ISR data is significant and will continue to increase. Despite uncertainties in ISR future budget and funding, especially with respect to manpower, the Air Force must learn to operate in an environment with limited resources. To improve mission effectiveness with reduced manpower, the 2010 "Technology Horizon" suggests the need for autonomous systems that will improve the situational awareness of analysts (i.e. decision-makers) and enhance their understanding and knowledge of the mission.

Some literature suggests automation and autonomy are synonyms [3, 12]. To distinguish automation from autonomy, the Air Force Research Laboratory (AFRL) Autonomy Science and Technology Strategy of 2013 [4], defines automation and autonomy as follows:

> Automation: The system functions with no/little human operator involvement; however, the system performance is limited to the specific actions it has been designed to do. Typically these are well-defined tasks that have predetermined responses (i.e., simple rule-based responses).
>
> Autonomy: Systems which have a set of intelligence-based capabilities that allow it to respond to situations that were not pre-programmed or anticipated in the design (i.e., decision-based responses). Autonomous systems have a degree of self-government and self-directed behavior (with the human's proxy for decisions).

In a static or predictive environment, automation and autonomy can be used interchangeably to analyze a fixed mission because the tasks are well-defined. However, the AF operates in complex and contested environments with complex machines and systems such as unmanned air vehicles (UAVs). For UAVs to operate in this environment not only is a pilot and sensor operator needed, but many other resources are required, such as: manning, administration, maintenance, and PED.

Current UAV success is partially attributed to having access to continuous and mostly uninterrupted imagery and data. Although, this is not the case for possible future operations because future operations need to be able to occur in dynamic, anti-access, area denial (A2AD) environments across multiple domains such as: air, land, and cyber. To meet future needs and to operate effectively, human-machine systems, such as UAVs, must be optimized to maintain a high caliber of mission performance. An optimization approach to understand and utilize autonomous systems is to increase use of our resources while decreasing cost. These systems will not replace the analysts, but will have the capability and freedom to self-direct with the analysts as a proxy for decisions to achieve mission objectives.

Thus, research in this area will be conducted through the use of 'self-governing' autonomous systems and validated by assessing the system's efficiency both prior to and after the automation for both the novice and expert analysts. In addition, this research will inform the Autonomy Science & Technology (S&T) Challenges for DoD

and Industry Partners [3, 4] by enabling and calibrating trust between human and machine; creating an environment for flexible and effective decision making; advancing data-driven analytics; and expanding test, evaluation, validation, and verification. These improvements will be realized in a cost effective simulated environment across multiple operational domains and incorporate scenario-based testing. Providing the appropriate modeling and design for data collection and analysis becomes paramount, and sampling characteristics for the construction of appropriate modeling are required. The research objectives proposed in this dissertation are the first step towards achieving this goal.

The remainder of this dissertation is outlined as follows. Chapter II is a review of the statistical modeling tool and technique, HLM, and an overview of current sample size studies and requirements for HLM models. Chapter III presents the Level-2, Level-3, and Level-4 HLM general model, assumptions, and derives the sample size requirements for a Level-4 HLM with a single predictor at all levels (individual, group, unit, and organization). As a byproduct, requirements for a Level-2 and Level-3 model with equally weighted single predictor at Level 2 and 3 are proposed. Chapter IV presents the effects of re-sampling based methods for up to a Level-3 HLM and provides recommendations on when such techniques are appropriate. Chapter V gives a notional Level-4 HLM example. Finally, Chapter VI provides a final discussion and and future work.

II. Background

This section reviews the structure of Hierarchical Linear Models (HLMs) and current sample size guidelines for design considerations. To develop the requirements and considerations for models, this research proposes using HLMs to analyze a system's performance. The following sections describe the HLMs and general properties needed to expand and complete the proposed research objective.

2.1 Hierarchical Linear Model (HLM)

Hierarchical Linear Models (HLMs), also known as multilevel models, are an extension of regression analyses. They are used to analyze nested data sets with complex patterns of variability and may be used to analyze relations among different levels (i.e., Level-1, Level-2, Level-3, and Level-4). In HLMs, the data are divided into different levels in which the individuals, or subjects, at Level-1 may be dependent because they are nested into larger clusters, called groups. The use of HLMs to assess nested data is preferred over standard multivariate analysis because the dependency of the data violates the assumption of multivariate independence of all observations [10, 14, 15, 17, 19, 26, 31, 34, 42, 37, 35]. Further, modeling all levels simultaneously makes for efficient estimation of the effects (and variability) associated within and between each level of the HLM.

Notationally, to be consistent with the literature, the lowest level, Level-1, represents the individuals or subjects, Level-2 represents the group (i.e. cluster of individuals), Level-3 represents the unit (i.e. cluster of groups), and Level-4 represents the organization (i.e. cluster of units). As the number of levels increases, the higher levels in which subjects are nested are denoted with subsequent level numbering such as Level-1, Level-2, Level-3, Level-4, and so on.

HLMs allow researchers to simultaneously study the effects of group level variables and individual level variables. That is, HLMs measure how variables at one level affect relations occurring at another. These types of models consider error terms at each level that normal regression does not. These error terms are no longer independent across levels, but nested. Each level of nested data is associated with variability that has a distinct interpretation and affects the model parameter estimates [45]. For example, a school district's math score can be thought of as the following Level-4 HLM (Figure 1): student math scores (Level-1) are nested within classroom math scores, classroom math scores (Level-2) are nested within school math scores, and school math scores (Level-3) are nested within the district math score (Level-4).

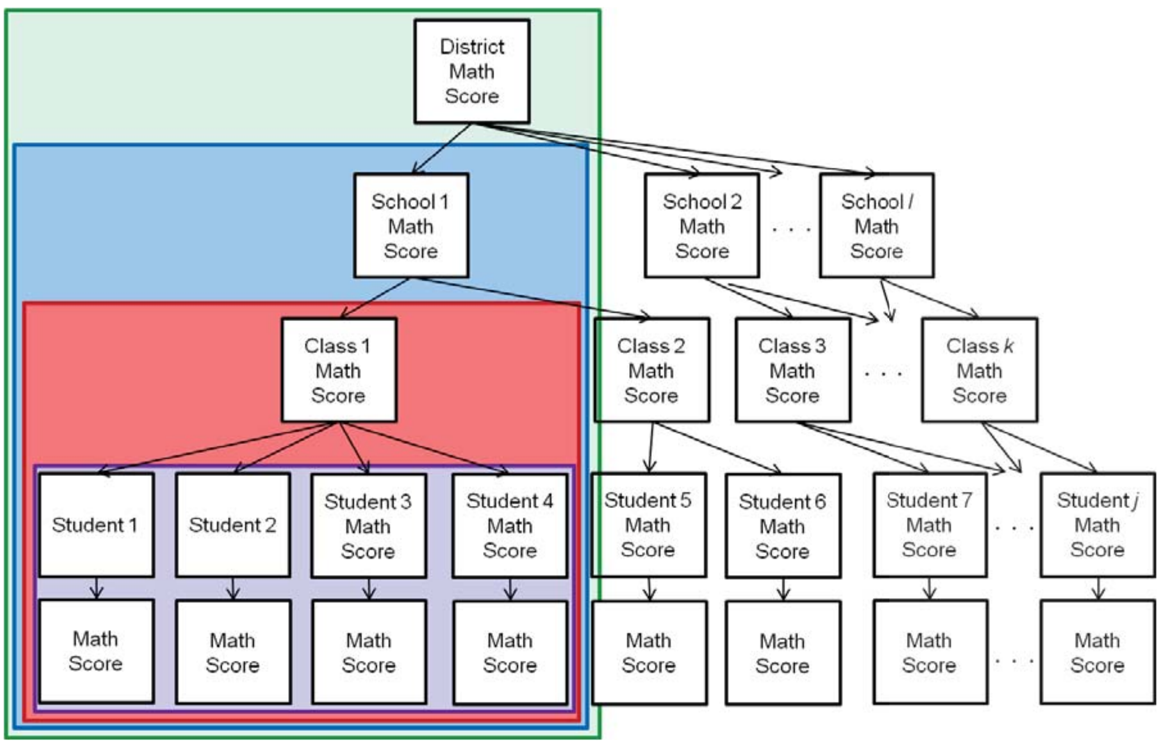

Figure 1. Conceptual image of HLM Level-4 school district math scores

Conceptually, it is useful to think of HLMs as a hierarchical system of regression equations. Although, HLM is an extension of multiple linear regression, the model is more complicated. The predictors or explanatory variables, are measured at all

levels (i.e. Level-1, Level-2, Level-3 or Level-4), the number of parameters is larger, cross-level interactions must be considered, and there are one or more error terms at each level.

The cross-level interaction terms allow researchers to test hypotheses about how variables measured at one level affect relations occurring at another level. For example, within social research studies of schools, a researcher might be interested in whether there is an effect between student math scores (i.e. Level-1) and a teacher's education level (e.g. Level-2), or whether there is an effect between a student's math score (i.e. Level-1) and whether the school offers private or public education (i.e. Level-3).

These relations can be represented pictorially through the diagrams of path models [44]. Path, or structural, models are graphical representations of the equations that relate dependent variables to their independent explanatory variables. These models allow researchers to visually see theories or hypotheses, and physically manipulate the models to test changes. Underlying the path model is a system of equations, also known as the measurement model.

Path models are composed of two types of variables (manifest and latent) and directional arrows (both single- and double- headed). Manifest variables, graphically denoted by squares and rectangles, are observed variables that are directly measured. Whereas, latent variables, graphically denoted by circles and ovals, are unobserved variables that are indirectly measured. That is, latent variables are inferred by the responses of indicators. Indicators are manifest variables used to measure the latent variables. The indicators must clearly measure the same underlying construct (i.e. be correlated with one another) and have been validated through previous research. For example in Figure 2, within the PED, the possible indicator variables (number of details, number of Essential Elements of Information (EEIs) verbalized, and time from

event occurrence to spoken) measure workload for the Eyes On analyst (a position within the PED cell of DGS-SOF, which is discussed in detail in Chapter V). Other examples of indicator variables for the Eyes On analyst are objective (e.g. number of units produced per hour) and subjective measures (e.g. responses to a questionnaire).

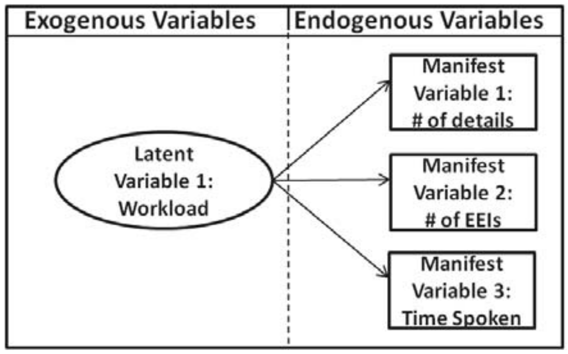

Figure 2. Example path model of possible endogenous variables that measure the exogenous variable (i.e. indicator variables) workload for the Eyes On Analysts.

The model representation for between levels, also known as a between model, is defined by single- and double- headed arrows. Single-headed arrows represent the impact of one variable on another. That is, single-headed arrows point to endogenous (dependent) variables, variables whose variability is predicted to be casually affected by other variables in the model. Independent variables, also known as exogenous variables, are variables that are influenced only by external factors that lie outside of the casual model. Therefore, single-headed arrows do not point to exogenous variables, unless referring to residual error.

A double-headed arrow represents a bidirectional casual relationship that makes no hypothesis as to which variable influences which. In other words, a double headed-arrow connecting two variables represents a covariance or a correlation between the variables.

Within path models, the independent variables at a lower level (e.g. Level-2) are represented as dependent variables at the next level (e.g. Level-3). Pictorially, they are circles and ovals at the next level, instead of the prior squares and rectangles.

That is, manifest variables at a lower level become latent variables at the higher level. This is illustrated in the path models and shown in the measurement models of the next section.

2.2 General Level-4 Hierarchical Linear Model (HLM) Measurement Model

Each of the four levels considered with multiple predictors has an associated HLM diagram and measurement model. This section outlines the associated HLM diagrams and measurement models for each level of the Level-4 HLM by building the model one level at a time. In general, Level-1 predictors, A_{ijkl}, vary such that $i = 1, ..., n$, Level-2 predictors, X_{ijkl}, vary such that $j = 1, ..., g$, Level-3 predictors, W_{ijkl}, vary such that $k = 1, ..., h$, and Level-4 predictors, Z_{ijkl}, vary such that $l = 1, ..., f$.

General Level-1 HLM Measurement Model for n Individual Predictors at Level-1.

A Level-1 structural model, shown in Figure 3, has n manifest exogenous variables (denoted A_{1jkl}, A_{2jkl}, ..., A_{njkl}) and one response endogenous variable (denoted Y_{ijkl}). Y_{ijkl} is measured by the linear combination of coefficients $\pi_{1jkl}, \pi_{2jkl}, ..., \pi_{njkl}$ and manifest variables A_{1jkl}, A_{2jkl}, ..., A_{njkl}, represented by single-headed arrows. The manifest variables A_{1jkl}, A_{2jkl}, ..., A_{njkl} are correlated and the correlation is represented by double-headed arrows.

Within each individual unit i, the general Level-1 HLM models the individual unit of interest as a function of individual level predictors plus a random individual-level

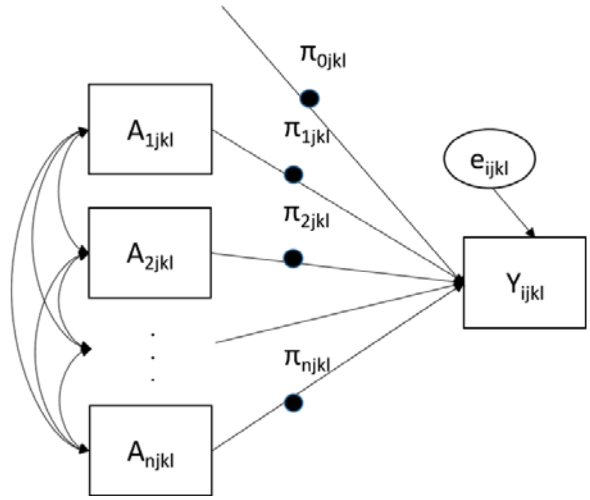

Figure 3. General Level-1 HLM model for n individual predictors such that: the manifest variables $A_{1jkl}, A_{2jkl}, ..., A_{njkl}$ are correlated, $A_{1jkl}, A_{2jkl}, ..., A_{njkl}$ measure Y_{ijkl}, Y_{ijkl} has an associated error (represented by a single arrow in the diagram), and each manifest variable has a coefficient represented as $\pi_{1jkl}, \pi_{2jkl}, ..., \pi_{njkl}$ in the diagram and measurement model.

error. That is, the Level-1 HLM for n individual predictors is:

$$\begin{aligned} Y_{ijkl} &= \pi_{0jkl} + \pi_{1jkl}A_{1jkl} + \pi_{2jkl}A_{2jkl} + ... + \pi_{njkl}A_{njkl} + e_{ijkl} \\ &= \pi_{0jkl} + \sum_{i=1}^{n} \pi_{ijkl}A_{ijkl} + e_{ijkl} \end{aligned} \tag{1}$$

where:

Y_{ijkl} is the outcome variable of individual i, in group j, unit k, and organization l;

π_{0jkl} is the intercept for group j, unit k, and organization l;

A_{ijkl} are the $i = 1, ..., n$ Level-1 predictors (individual-level explanatory variables);

π_{ijkl} are the Level-1 coefficients that indicate the direction and strength of association between each Level-1 predictor, A_{ijkl}, and the outcome in group jkl;

e_{ijkl} is the Level-1 random effect that represents the deviation of individual $ijkl$ from the predicted value based on the individual-level model. Such that: $e_{ijkl} \sim$

$N(0, \sigma^2_{e_{ijkl}})$.

General Level-2 HLM Measurement Model for n Individual Predictors at Level-1 and g Group Predictors at Level-2.

The second level of an HLM shown in Figure 4, has g manifest exogenous variables (denoted X_{ijkl} such that $j = 1, 2, ..., g$) and ng response endogenous variable (denoted π_{1jkl}, $\pi_{2jkl}, ..., \pi_{njkl}$). The response variables are measured by manifest variable X_{ijkl}, and represented by single-headed arrows, such that X_{i1kl}, X_{i2kl}, ..., X_{igkl} are correlated. Each manifest variable has a coefficient denoted as $\beta_{00kl}, \beta_{01kl}, ..., \beta_{ngkl}$.

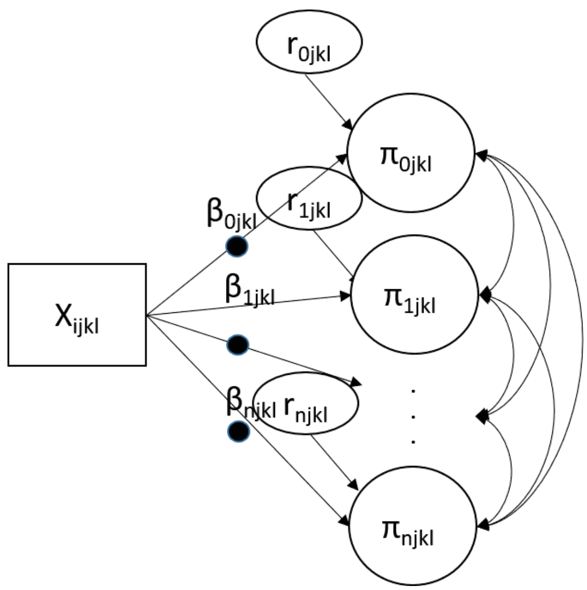

Figure 4. Level-2 HLM model for n individual predictors on Level-1 and g group predictors on Level-2 such that: the manifest variables $X_{i1kl}, X_{i2kl}, ...X_{igkl}$, illustrated as X_{igkl}, are correlated (not shown), $X_{i1kl}, X_{i2kl}, ..., X_{igkl}$ measure $\pi_{1jkl}, ..., \pi_{njkl}$, and each manifest variable has a coefficient represented as $\beta_{0jkl}, \beta_{1jkl}, ..., \beta_{njkl}$ in the diagram.

Each of the Level-1 coefficients, π_{ijkl}, defined in the Level-1 HLM of Equation 1, becomes an outcome variable in the Level-2 HLM measurement model where:

$$\pi_{0jkl} = \beta_{00kl} + \beta_{01kl}X_{i1kl} + \beta_{02kl}X_{i2kl} + ... + \beta_{0gkl}X_{igkl} + r_{0jkl},$$
$$\pi_{1jkl} = \beta_{10kl} + \beta_{11kl}X_{i1kl} + \beta_{12kl}X_{i2kl} + ... + \beta_{1gkl}X_{igkl} + r_{1jkl},$$
$$\vdots$$
$$\pi_{njkl} = \beta_{n0kl} + \beta_{n1kl}X_{i1kl} + \beta_{n2kl}X_{i2kl} + ... + \beta_{ngkl}X_{igkl} + r_{njkl},$$

such that:

$$\pi_{ijkl} = \beta_{i0kl} + \sum_{j=1}^{g} \beta_{ijkl}X_{ijkl} + r_{ijkl} \tag{2}$$

where:

β_{i0kl} is the intercept for unit k in modeling the team effect π_{ijkl};

X_{ijkl} are the $j = 1, ..., g$ Level-2 predictors (group-level explanatory variable);

$\beta_{.jkl}$ are the Level-2 coefficients that indicate the direction and strength of association between each Level-2 predictor, X_{ijkl}, and $\pi_{.jkl}$;

r_{ijkl} is the Level-2 random effect that represents the deviation of group jkl's Level-1 coefficient, $\pi_{.jkl}$, from its predicted value based on the group-level model. Assume that the r_{ijkl}'s are normally distributed such that: $r_{ijkl} \sim N(0, \sigma^2_{r_{ijkl}})$.

By substitution of Equation 2 into Equation 1, the combined Level-2 HLM for n individual predictors on Level-1 and g predictors on Level-2 is

$$\begin{aligned} Y_{ijkl} = {} & (\beta_{00kl} + \beta_{01kl}X_{1kl} + \beta_{02kl}X_{2kl} + ... + \beta_{0gkl}X_{gkl} + r_{0jkl}) \\ & + (\beta_{10kl} + \beta_{11kl}X_{.1kl} + \beta_{12kl}X_{.2kl} + ... + \beta_{1gkl}X_{.gkl} + r_{1jkl})A_{1jkl} \\ & + ... + (\beta_{n0kl} + \beta_{n1kl}X_{.1kl} + \beta_{n2kl}X_{.2kl} + ... + \beta_{ngkl}X_{.gkl} + r_{njkl})A_{njkl} + e_{ijkl} \end{aligned} \tag{3}$$

such that: $Cov(e_{ijkl}, r_{ijkl}) = 0$, $\forall ijkl$. Note that the product of A_{ijkl}'s and X_{ijkl}'s represent the cross-level interactions.

General Level-3 HLM Measurement Model for n Individual Predictors at Level-1, g Group Predictors at Level-2, and h Unit Predictors at Level-3.

The 3rd level of an HLM, shown in Figure 5, has h manifest exogenous variables (denoted W_{ijkl} such that $k = 1, 2, ..., h$) and ngh response endogenous variable (denoted β_{00kl}, $\beta_{01kl}, ..., \beta_{ngkl}$). The response variables are measured by manifest variable W_{ijkl}, and represented by single-headed arrows, such that W_{ij1l}, W_{ij2l}, ..., W_{ijhl} are correlated. Each manifest variable has a coefficient denoted $\gamma_{000l}, \gamma_{001l}, ..., \gamma_{nghl}$.

Each of the Level-2 coefficients, $\beta_{..kl}$, defined in the general Level-2 HLM of Equation 3, becomes an outcome variable in the Level-3 HLM measurement model where:

$$\begin{aligned}
\beta_{00kl} &= \gamma_{000l} + \gamma_{001l}W_{ij1l} + \gamma_{002l}W_{ij2l} + ... + \gamma_{00hl}W_{ijhl} + u_{00kl}, \\
\beta_{01kl} &= \gamma_{010l} + \gamma_{011l}W_{ij1l} + \gamma_{012l}W_{ij2l} + ... + \gamma_{01hl}W_{ijhl} + u_{01kl}, \\
&\vdots \\
\beta_{ngkl} &= \gamma_{ng0l} + \gamma_{ng1l}W_{ij1l} + \gamma_{ng2l}W_{ij2l} + ... + \gamma_{nghl}W_{ijhl} + u_{ngkl},
\end{aligned}$$

such that:

$$\beta_{ijkl} = \gamma_{ij0l} + \sum_{k=1}^{h} \gamma_{ijkl}W_{ijkl} + u_{ijkl} \tag{4}$$

where:

γ_{ij0l} is the overall intercept in modeling the unit effect β_{ijkl};

W_{ijkl} are the $k = 0, 1, ..., h$ Level-3 predictors (unit-level explanatory variable);

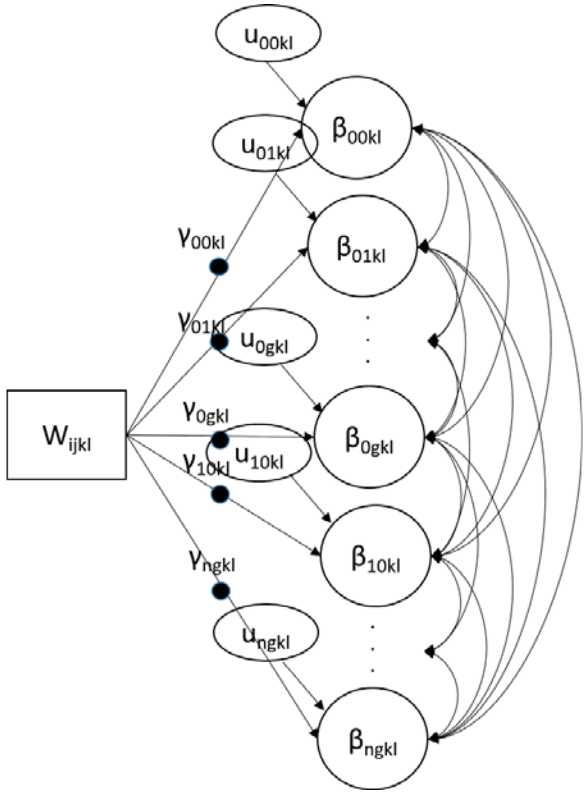

Figure 5. Level-3 HLM model for n individual predictors on Level-1, g group predictors on Level-2, and h unit predictors on Level-3 such that: the manifest variables $W_{ij11}, W_{ij21}, ...W_{ijh1}$, illustrated as W_{ijk1}, are correlated (not shown), $W_{ij11}, W_{ij21}, ..., W_{ijh1}$ measure $\beta_{00kl}, \beta_{01kl}, ..., \beta_{ngkl}$, and each manifest variable has a coefficient $\gamma_{00kl}, \gamma_{01kl}, ..., \gamma_{ngkl}$ in the diagram.

γ_{ijkl} are the Level-3 coefficients that indicate the direction and strength of association between each Level-3 predictor, W_{ijkl}, and β_{ijkl};

u_{ijkl} are the Level-3 random effect that represents the deviation of unit k's Level-2 coefficient, β_{ijkl}, from its predicted value based on the unit-level model. Assume that the u_{ijkl}'s are normally distributed such that: $u_{ijkl} \sim N(0, \sigma^2_{u_{ijkl}})$.

By substitution of Equation 4 into Equation 3, the Level-3 HLM with n individual predictors on Level-1, g group predictors on Level-2, and h unit predictors on Level-3 is given by:

$$
\begin{aligned}
Y_{ijkl} = &((\gamma_{000l} + \gamma_{001l}W_{1l} + \gamma_{002l}W_{2l} + ... + \gamma_{00hl}W_{hl} + u_{00kl}) \\
&+ (\gamma_{010l} + \gamma_{011l}W_{1l} + \gamma_{012}W_{2l} + ... + \gamma_{01hl}W_{hl} + u_{01kl})X_{1kl} + ... \\
&+ (\gamma_{0g0l} + \gamma_{0g1l}W_{1l} + \gamma_{0g2l}W_{2l} + ... + \gamma_{0ghl}W_{hl} + u_{0gkl})X_{nkl} + r_{0jkl}) \\
&+ \sum_{k=1}^{g}\sum_{j=1}^{g}\sum_{i=1}^{n}((\gamma_{ij0l} + \gamma_{ijk}W_{.1k} + \gamma_{ijk}w_{.2k} + ... + \gamma_{ijk}W_{hl})X_{jkl} + r_{ijkl})A_{ijkl} + e_{ijkl},
\end{aligned}
\tag{5}
$$

such that: $Cov(e_{ijkl}, r_{ijkl}) = Cov(e_{ijkl}, u_{ijkl}) = Cov(r_{ijkl}, u_{ijkl}) = 0$, $\forall ijkl$. Note that the product of A_{ijkl}'s, X_{ijkl}'s, and $W_{..kl}$'s represent the cross-level interactions.

General Level-4 HLM Measurement Model for n Individual Predictors at Level-1, g Group Predictors at Level-2, h Unit Predictors on Level-3, and f Organization Predictors at Level-4.

The 4th level of an HLM, shown in Figure 6, has f manifest exogenous variables (denoted Z_{ijkl} such that $l = 1, 2, ..., f$) and $nghf$ response endogenous variables (denoted $\gamma_{000l}, \gamma_{001l}, ..., \gamma_{nghl}$. The response variables are measured by manifest variable Z_{ijkl}, represented by single headed arrows, such that $Z_{ijk1}, Z_{ijk2}, ..., Z_{ijkf}$ are correlated. Each manifest variable has a coefficient denoted $\delta_{0000}, \delta_{0001}, ..., \delta_{nghf}$.

Each of the Level-3 coefficients, γ_{ijkl}, defined in the general Level-3 HLM of Equation 5, becomes an outcome variable in the Level-4 HLM measurement model where:

$$
\begin{aligned}
\gamma_{000l} &= \delta_{0000} + \delta_{0001}Z_{ijkl} + \delta_{0002}Z_{ijk2} + ... + \delta_{000f}Z_{ijkf} + v_{000l}, \\
\gamma_{001l} &= \delta_{0010} + \delta_{0011}Z_{ijk1} + \delta_{0012}Z_{ijk2} + ... + \delta_{001f}Z_{ijkf} + v_{001l}, \\
&\vdots \\
\gamma_{nghl} &= \delta_{ngh0} + \delta_{ngh1}Z_{ijk1} + \delta_{ngh2}Z_{ijk2} + ... + \delta_{nghf}Z_{ijkf} + v_{nghl},
\end{aligned}
$$

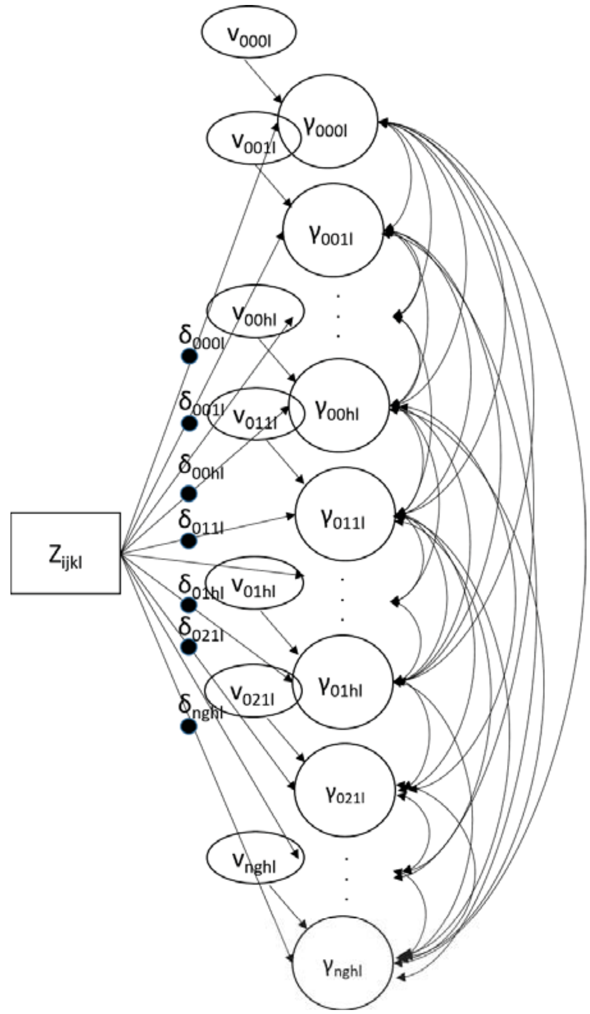

Figure 6. General Level-4 HLM diagram for n individual predictors on Level-1, g group predictors on Level-2, h unit predictors on Level-3, and f organization predictors on Level-4 such that: the manifest variables $Z_{ijk1}, Z_{ijk2}, ...Z_{ijkf}$, illustrated as Z_{ijkl}, are correlated (not shown), $Z_{ijk1}, Z_{ijk2}, ..., Z_{ijkf}$ measure $\gamma_{000l}, \gamma_{001l}, ..., \gamma_{nghl}$, and each manifest variable has a coefficient $\delta_{000l}, \delta_{001l}, ..., \delta_{nghl}$ in the diagram.

such that:

$$\gamma_{ijkl} = \delta_{ijk0} + \sum_{l=1}^{f} \delta_{ijkl} Z_{ijkl} + v_{ijkl} \tag{6}$$

where:

δ_{ijk0} is the intercept for organization l in modeling the unit effect γ_{ijkl};

Z_{ijkl} are the $l = 0, 1, ..., f$ Level-4 predictors (organization-level explanatory variable);

δ_{ijkl} are the Level-4 coefficients that indicate the direction and strength of association between each Level-4 predictor, Z_{ijkl}, and the γ_{ijkl};

v_{ijkl} are the Level-4 random effect that represents the deviation of organization l's Level-3 coefficient, γ_{ijkl}, from its predicted value based on the organization-level model. Assume that the v_{ijkl}'s are normally distributed such that: $v_{ijkl} \sim N(0, \sigma^2_{v_{ijkl}})$.

By substitution of Equation 6 into Equation 5, the Level-4 HLM with n individual predictors on Level-1, g group predictors on Level-2, h unit predictors on Level-3, and f organizational predictors on Level-4, is given by:

$$
\begin{aligned}
Y_{ijkl} = {} & (((\delta_{0000} + \delta_{0001} Z_{ijk1} + \delta_{0002} Z_{ijk2} + ... + \delta_{000f} Z_{ijkf} + v_{000l}) \\
& + (\delta_{0010} + \delta_{0011} Z_{ijk1} + \delta_{0012} Z_{ijk2} + ... + \delta_{001f} Z_{ijkf} + v_{001l}) W_{ij1l} + ... \\
& + (\delta_{00h0} + \delta_{00h1} Z_{ijk1} + \delta_{00h2} Z_{ijk2} + ... + \delta_{00hf} Z_{ijkf} + v_{00hl}) W_{ijhl} + u_{00kl}) \\
& + ((\delta_{0100} + \delta_{0101} Z_{ijk1} + \delta_{0102} Z_{ijk2} + ... + \delta_{010f} Z_{ijkf} + v_{010l}) + ... \\
& + (\delta_{0gh0} + \delta_{0gh1} Z_{ijk1} + \delta_{0gh2} Z_{ijk2} + ... + \delta_{0ghf} Z_{ijkf} + v_{0ghl}) W_{ijhl} + u_{0gkl}) X_{ijkl} + r_{0jkl}) \\
& + \sum_{l=1}^{f} \sum_{k=1}^{h} \sum_{j=1}^{g} \sum_{i=1}^{n} (((\delta_{ijk0} + \delta_{ijk1} Z_{ijkl} + \delta_{ijk2} Z_{ijk2} + ... + \delta_{ijkl} Z_{ijkl}) W_{ijkl} \\
& + ... + u_{ijkl}) X_{ijkl} + r_{ijkl}) A_{ijkl} + e_{ijkl}
\end{aligned}
\tag{7}
$$

such that:

$Cov(e_{ijkl}, v_{ijkl}) = Cov(e_{ijkl}, u_{ijkl}) = Cov(e_{ijkl}, r_{ijkl}) = Cov(r_{ijkl}, v_{ijkl}) = Cov(r_{ijkl}, u_{ijkl}) = Cov(u_{ijkl}, v_{ijkl}) = 0, \forall ijkl$. Note that the product of A_{ijkl}'s, X_{ijkl}'s, W_{ijkl}'s, and Z_{ijkl}'s represent the cross-level interactions.

Intraclass Correlation.

The accuracy of the parameter estimates and the amount of dependency within HLMs is measured through the intraclass correlation (ICC), denoted ρ [16]. For a Level-2 HLM, the ICC is the expected correlation between any two randomly chosen individuals in the same group [19]. To determine if additional levels within the HLM are useful to assess a response variable of interest, the variance for a given level is partitioned into within- and between- cluster components. Formally, the ICC is defined as the proportion of individual-level and group-level variance compared to the total variance. That is, the ICC values for a Level-2 HLM are as follows:

Proportion of variance of individuals for a Level-2 HLM (Level-1)

$$ICC2_1 = \sigma^2_{e_{ij}}/(\sigma^2_{e_{ij}} + \sigma^2_{r_{ij}}) \tag{8}$$

Proportion of variance among groups for a Level-2 HLM (Level-2)

$$ICC2_2 = \sigma^2_{r_{ij}}/(\sigma^2_{e_{ij}} + \sigma^2_{r_{ij}}) \tag{9}$$

such that the within-variance and between-variance are denoted $\sigma^2_{e_{ij}}$ and $\sigma^2_{r_{ij}}$, respectively. For a Level-2 HLM, if there is little or no variation in the outcome between Level-2 groups, then there is no need for Level-2 variables in the HLM analysis. In general, the ICC ranges from 0 to 1 such that larger values represent higher correlation. Depending on how ICC is calculated, in general, a low ICC close to zero implies that individuals (Level-1) from the same group (Level-2) are non-homogeneous. A high ICC close to 1 indicates there is a strong relationship between individuals within the same group. That is, the groups are relatively homogeneous.

Although ICC values are study and application dependent, in general, previous Level-2 HLM analyses have considered ICC values to be low, medium, and high for 0.1,

0.3, and 0.5, or 0.7, respectively [6, 27, 28, 42]. Using these assumed ICC values and a fixed Level-1 variance distribution, denoted $\sigma^2_{e_{ij}}$, the Level-2 variance distribution, $\sigma^2_{r^2_{ij}}$, can be determined for low, medium, and high ICC. This calculation is useful for sample size calculations. In practice, variances are observed and ICCs are calculated from these observed values.

Because the ICC indicates the proportion of the variance explained by the level of interest, ICC values can be captured for each level in an HLM. Therefore, the Level-2 HLM ICC formula can be extended to Level-3 and Level-4 HLMs. For greater than Level-2 ICC calculations, such as Level-3, if the Level-2 HLM variables are not significant, but the Level-3 variables are, then simple linear regression will not work and the need fo rmulti-level modeling is necessary. The ICC values for a Level-3 HLM are as follows:

Proportion of variance of individuals for a Level-3 HLM (Level-1)

$$ICC3_1 = \sigma^2_{e_{ijk}}/(\sigma^2_{e_{ijk}} + \sigma^2_{r_{ijk}} + \sigma^2_{u_{ijk}}) \tag{10}$$

Proportion of variance among groups for a Level-3 HLM (Level-2)

$$ICC3_2 = \sigma^2_{r_{ijk}}/(\sigma^2_{e_{ijk}} + \sigma^2_{r_{ijk}} + \sigma^2_{u_{ijk}}) \tag{11}$$

Proportion of variance among units for a Level-3 HLM (Level-3)

$$ICC3_3 = \sigma^2_{u_{ijk}}/(\sigma^2_{e_{ijk}} + \sigma^2_{r_{ijk}} + \sigma^2_{u_{ijk}}) \tag{12}$$

The ICC values for a Level-4 HLM are as follows:

Proportion of variance of individuals for a Level-4 HLM (Level-1)

$$ICC4_1 = \sigma^2_{e_{ijkl}} / (\sigma^2_{e_{ijkl}} + \sigma^2_{r_{ijkl}} + \sigma^2_{u_{ijkl}} + \sigma^2_{v_{ijkl}}) \tag{13}$$

Proportion of variance among groups for a Level-4 HLM (Level-2)

$$ICC4_2 = \sigma^2_{r_{ijkl}} / (\sigma^2_{e_{ijkl}} + \sigma^2_{r_{ijkl}} + \sigma^2_{u_{ijkl}} + \sigma^2_{v_{ijkl}}) \tag{14}$$

Proportion of variance among units for a Level-4 HLM (Level-3)

$$ICC4_3 = \sigma^2_{u_{ijkl}} / (\sigma^2_{e_{ijkl}} + \sigma^2_{r_{ijkl}} + \sigma^2_{u_{ijkl}} + \sigma^2_{v_{ijkl}}) \tag{15}$$

Proportion of variance among organizations for a Level-4 HLM (Level-4)

$$ICC4_4 = \sigma^2_{v_{ijkl}} / (\sigma^2_{e_{ijkl}} + \sigma^2_{r_{ijkl}} + \sigma^2_{u_{ijkl}} + \sigma^2_{v_{ijkl}}) \tag{16}$$

This research used the ICC definition based on proportion of variance, as given in Equation 8 to 16, to capture the ICC values, which is most common to HLMs. However, the ICCs can be calculated differently and each form of ICC has distinct assumptions and interpretations. Based on the type of study, McGraw and Wong (1996), outlined questions to best determine which ICC to use [32]. The ICC forms detailed in [32] are those calculated within software such as SPSS [43].

In practice, the ICC would not be known prior to a study. Therefore, in this research the error variance distribution terms were identified for each level of interest. For example, for a Level-2 HLM analysis both $\sigma^2_{e_{ij}}$ and $\sigma^2_{r_{ij}}$ were assumed and used to calculate the ICC. All ICC values within this research were found to be moderate (between 0.33 to 0.50) and comparable to previous research.

Estimation of Maximum Likelihood (ML).

In HLM analysis, estimation of the model parameters, both regression coefficients and variance terms, are typically obtained by maximum likelihood (ML). ML estimation methods are commonly used in HLM analysis because they are robust against model violations (e.g. non-normal errors) with large enough sample sizes and identify values that are most consistent with the sample data. ML methods, such as Restricted Maximum Likelihood (REML) and Full Maximum Likelihood (FML), are commonly used in HLM analysis, but due to their asymptotic nature, large sample sizes are needed. Therefore, small sample sizes can affect the accuracy of the HLM estimates and the associated standard errors. In the FML method, the regression coefficients and the variance components are included in the likelihood function, whereas in the REML method only the variance terms are included in the likelihood function and the regression coefficients are estimated in another step. That is, the REML likelihood function estimates the variance terms after removing the fixed effects from the model [16, 39]. Though in practice the difference between the two methods is small, some researchers state REML is preferred because it takes the uncertainty in the fixed parameters into account when estimating the random parameters [20, 23]. Thus, in theory REML should lead to better estimates of the variance components, especially when the number of groups is small [35]. Whereas, others state FML is preferred because computations are generally easier [21]. We note that most software such as Matlab, MPlus, and SAS can estimate parameters with both with the FML and REML methods. This research utilized the maximum likelihood REML because not only are small samples sizes considered, which REML provides better results for than FML, but REML was the ML of choice for other comparable research.

2.3 Current HLM Statistical Power Sample Size Requirements

Sample size determinations and collection processes are important to both observational and experimental studies because, for example, to interview 10 persons from 100 regions is easier and more cost effective than interviewing 1,000 people randomly. To determine sample size requirements, Maas and Hox (2005) suggest examining the accuracy of the parameter estimates and corresponding standard errors based on the number of clusters chosen for each level [28]. Here in this research, clusters are used to generally describe the different level groupings (i.e., group, unit, and organization) as a whole. In HLM analysis, determining the sample size is more difficult because there are parameters at more than one level, and the model includes fixed and random parts [21]. Sample size recommendations in testing is based on detectable differences (from the estimated coefficient $\hat{\mu}$ to the hypothesized parameter value μ_0) and estimated confidence intervals. For studies to have large enough detectable differences, sample size planning is necessary to reduce Type II (failing to reject a null hypothesis i.e., false negative) errors. To test the hypothesis that a particular parameter has no effect, a test statistic is computed for that parameter. In HLM, the test statistic is the estimated coefficient to its estimated standard error $t^* = \frac{\hat{\mu}}{s.e.(\hat{\mu})}$ [24]. Note, this is the test statistic when $H_0 : \mu = 0$. That is, whether or not the particular predictor variable has an effect on the response. If testing another value, say μ_0, the best statistic is in general $t^* = \frac{\hat{\mu}-\mu_0}{s.e.(\hat{\mu})}$. The hypothesis tests to determine significance for a fixed effect in general is:

$$H_0 : \mu = 0 \text{ and } H_A : \mu \neq 0$$

with $t^* = \frac{\hat{\mu}}{s.e.(\hat{\mu})}$, such that the decision rule with significance level α is:

$$|t^*| \leq t(1-\alpha/2; n-2) \text{ then conclude } H_0$$
$$|t^*| > t(1-\alpha/2; n-2) \text{ then conclude } H_A.$$

Note that for a Level-2 HLM test, the hypothesis tests to determine significance for a fixed effect is:

$$H_0 : \beta_{ij} = 0 \text{ and } H_A : \beta_{ij} \neq 0,$$

with $t^* = \frac{\hat{\beta}_{ij}}{s.e.(\hat{\beta}_{ij})}$. For a Level-3 HLM test, the hypothesis tests to determine significance for a fixed effect is:

$$H_0 : \gamma_{ijk} = 0 \text{ and } H_A : \gamma_{ijk} \neq 0$$

with $t^* = \frac{\hat{\gamma}_{ijk}}{s.e.(\hat{\gamma}_{ijk})}$, and for a Level-4 HLM test, the hypothesis tests to determine significance for a fixed effect is:

$$H_0 : \delta_{ijkl} = 0 \text{ and } H_A : \delta_{ijkl} \neq 0$$

with $t^* = \frac{\hat{\delta}_{ijkl}}{s.e.(\hat{\delta}_{ijkl})}$.

The statistical power, π, of a hypothesis is the probability of rejecting H_0 given that H_0 is false. The power of a statistical test is a function of the type I error (α), standard error ($s.e.(\hat{\mu})$) and the population estimated effect size ($\hat{\mu} - \mu$), where $\hat{\mu}$ is estimated from the model and μ_0 is the parameter of interest. These are represented in the following equation [13]:

$$\frac{\hat{\mu} - \mu_0}{s.e.(\hat{\mu})} \approx z_{1-\alpha/2} + z_\pi \tag{17}$$

This implies

$$z_\pi \approx -z_{1-\alpha/2} + \frac{\hat{\mu} - \mu_0}{s.e.(\hat{\mu})}. \tag{18}$$

Under the two-sided hypothesis test, H_0 is rejected when:

$$\begin{aligned}
P\left(\left|\frac{\hat{\mu} - \mu_0}{s.e.(\hat{\mu})}\right| > z_{1-\alpha/2}\right) &= 1 - P\left(\left|\frac{\hat{\mu} - \mu_0}{s.e.(\hat{\mu})}\right| \leq z_{1-\alpha/2}\right) \\
&= 1 - P\left(-z_{1-\alpha/2} \leq \frac{\hat{\mu} - \mu_0}{s.e.(\hat{\mu})} \leq z_{1-\alpha/2}\right) \\
&= 1 - P\left(-z_{1-\alpha/2} \leq \frac{\hat{\mu} - \mu}{s.e.(\hat{\mu})} + \frac{\mu - \mu_0}{s.e.(\hat{\mu})} \leq z_{1-\alpha/2}\right) \\
&= 1 - P\left(-z_{1-\alpha/2} \leq \frac{\hat{\mu} - \mu}{s.e.(\hat{\mu})} + \frac{\mu - \mu_0}{s.e.(\hat{\mu})} \leq z_{1-\alpha/2}\right) \\
&= 1 - P\left(-z_{1-\alpha/2} \leq \frac{\hat{\mu} - \mu}{s.e.(\hat{\mu})} + Z \leq z_{1-\alpha/2}\right) \\
&= 1 - P\left(-z_{1-\alpha/2} - \frac{\hat{\mu} - \mu}{s.e.(\hat{\mu})} \leq Z \leq z_{1-\alpha/2} - \frac{\hat{\mu} - \mu}{s.e.(\hat{\mu})}\right).
\end{aligned}$$

For large sample sizes (i.e., as $n \to \infty$), $\frac{\hat{\mu}-\mu}{s.e.(\hat{\mu})}$ follows a standard normal distribution when the alternative hypothesis is true. This implies

$$z_\pi \approx 1 - \Phi\left(-\frac{\hat{\mu} - \mu}{s.e.(\hat{\mu})} + z_{1-\alpha/2}\right), \tag{19}$$

where $z_{1-\alpha/2}$ is the z-value associated with the Type I error for a two-tailed test, z_π is the z-value associated with statistical power, estimated effect size is the magnitude of the true group difference, and standard error is the square root of the parameter variance [38, 42].

In HLM analysis, the parameter of interest, μ, represents generally the coefficients of the model. To calculate power of the coefficients, the variance of the estimators needs to be derived. The variance of the coefficient estimates are well defined for a single variable, as shown in Appendix A, and the formulas are extended to Level-3

and Level-4 HLM in the Chapter III.

Cohen (1988) suggests that power is moderate when estimated effect size is 0.50 and high when estimated effect size is at least 0.80 [11]. For a Level-2 HLM, to achieve a desired level of power given a relevant (hypothesized) estimated effect size and a chosen significance level (i.e., $\alpha = 0.05$) large samples are preferred in order to increase the precision of parameter estimates. To achieve a particular statistical power, the optimal sample sizes for each level must be determined. Currently, few sample size guidelines are referenced in the literature. Arend and Schafer (2019) found that HLM articles published between 2000 and 2016 in *Journal of Abnormal Psychology*, *Journal of Applied Psychology*, *Journal of Educational Psychology*, and *Journal of Personality and Social Psychology* consisted of 269 studies, of which only 9 studies included an exact determination of power [6]. Furthermore, these studies primarily exist for Level-2 HLMs, and the theory has not been translated to higher levels (e.g. Level-3 and Level-4) [7, 11].

The following referenced study conditions are for a single predictor at each level (Level-1, A_{ij}, and Level-2, X_{ij}), continuous predictors at each level, one cross-level interaction between predictors at each level ($A_{ij}X_{ij}$), and two random effects. Though, the associated study conditions (i.e. predictor distributions) are not always clearly addressed. The only case specifically specified consistently was $A_{ij} \sim N(0,1)$, $X_{ij} \sim N(0,1)$, $e_{ij} \sim N(0,1)$, and $r_{ij} \sim N(0,1)$.

Table 1. Level-2 sample size recommendations to achieve sufficient power of 80 %

		Level-2 Sample Size	Recommendations
Authors(s)	Reference(s)	Level-1	Level-2
Maas and Jox	[27, 28]	5 - 50	30 - 100
Kreft	[23]	30	30
Hox	[20]	20	50
Hoffman	[18]	20	50
		5	150

The sample size for each HLM level is defined as the number of clusters observed for that specific level [41]. The overall sample size total, N, is the product of the sample sizes at all the levels (e.g. $N = ng$ for Level-2 HLM). To achieve sufficient power, previous research for Level-2 HLM analysis found that a larger number of Level-2 groups appears to be more important than a large number of individuals per group (Level-1 sample size) [25, 33, 40]. Maas and Jox (2004, 2005) found that the appropriate number of Level-2 groups ranges from 30 to 100 and the number of Level-1 individuals range from 5 to 50 [27, 28].

Others suggest a common rule of thumb which is to have a minimum of 30 consistent clusters at Level-2 and at Level-1 [8, 23, 25]. Hox (1998) further refined this rule and recommended a minimum of 20 individuals (Level-1) for 50 groups (Level-2) [20]. Hoffman (1997) compared 30 individuals at Level-1 and 30 groups at Level-2 (for a total sample size of $N = 900$) to 5 individuals at Level-1 and 150 groups at Level-2 (for a total sample size of $N = 750$) and found that both approaches have the same power [18]. Though not shown, Snider and Bosker (2012) suggested a larger number of clusters at Level-2 and smaller number of clusters at Level-1 may still produce high levels of statistical power [42].

These sample size recommendations (summarized in Table Table 1) are contradictory to achievable samples sizes in many HLM applications. For many HLM analyses, the number of Level-2 groups is usually smaller than the number of Level-1 individuals. Further, as the number of levels increases (e.g. Level-3 and Level-4), the associated number of clusters decreases. For instance, in the AF DCGS application, the number of organizations is smaller than the number of units, the number of units is smaller than the number of teams (groups), and the number of teams is smaller than the number of analysts.

Sample size recommendations do not exist in the literature for Level-3 and Level-4

studies. However, there are statistical software applications, such as Optimal Design, which can compute statistical power for Level-2, Level-3 and Level-4 experimentation with treatment effects [22]. Treatment effects are primarily used for clinical type studies in which factor levels are varied and have associated variability equations with which to compute standard error used to calculate statistical power [30, 36]. However, these software calculations do not incorporate the goals of this research which focuses on continuous variables. In these studies, predictor variables have fixed, discrete levels and continuous predictor variables, such as those in the notional AF DCGS application, are not considered.

Typically, increasing the sample size improves model power and parameter estimates, but for most organizational research studies and populations of interest, this is not always possible as the sample may not exist or cannot be collected. Furthermore, financial constraints may not make sampling additional subjects feasible. In some applications, the sample size requirements may exceed the total population, especially in higher levels of the HLM. This research seeks to better define sample size requirements for Level-2, Level-3 and Level-4 HLMs, and define if resampling techniques may be used to achieve sufficient estimation and power for those scenarios in which sample size requirements cannot be met due to population or financial constraints.

III. Research Objective 1: Sample Size Requirements

This research considers HLMs with one predictor at each level and no predictor interactions within a given level. We assume that in each level, predictor effects are additive and therefore maybe represented through one predictor variable at each level. To understand the complexity of a Level-4 HLM in this scenario with a single predictor at each level and no predictor interactions within level, this research begins by first conceptualizing the Level-2 HLM. Then the Level-3 and Level-4 HLMs will be constructed. The Level-2, Level-3, and Level-4 HLMs were shown generally in the previous Chapter. For a Level-2 HLM, separate equations are developed for Level-1 (e.g. individuals) and for Level-2 (e.g. group) with a single predictor at Level-1 and Level-2 such that the predictors are independent at each level and across levels.

Within the following sections the standard error of the parameter estimates for Level-2, Level-3, and Level-4 are derived to determine the power of parameters by level expressed in Equation 19.

Level-1 of the HLM Measurement Model for 1 Individual Predictor at Level-1.

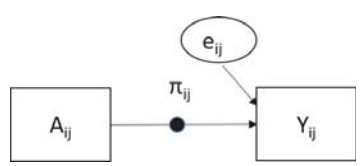

Figure 7. First level of an HLM structural model with 1 individual predictor at Level-2.

The Level-1 HLM equation, also known as the measurement model, for one individual predictor at Level-1, Figure 7, is:

$$Y_{ij} = \pi_{0j} + \pi_{1j}A_{ij} + e_{ij} \tag{20}$$

where:

Y_{ij} is the outcome variable of individual i and in group j;

π_{0j} is the intercept for group j;

A_{ij} is the Level-1 fixed predictor (individual-level explanatory) variable;

π_{1j} the Level-1 coefficient that indicates the direction and strength of association between the Level-1 predictor, A_{ij}, and the outcome in group j;

e_{ij} is the Level-1 random error that represents the deviation of individual ij from the predicted value based on the individual-level model, such that: $e_{ij} \sim N(0, \sigma_e^2)$.

Level-2 of the HLM Measurement Model for 1 Individual Predictor at Level-1 and 1 Group Predictor at Level-2.

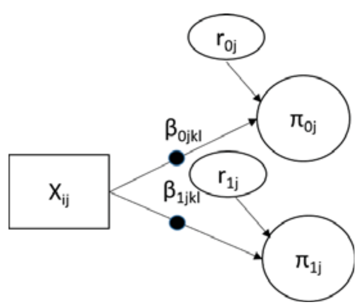

Figure 8. Second level of an HLM structural model with 1 group predictor at Level-2.

For Figure 8, the Level-1 coefficients (π_{0j} and π_{1j}), defined in Level-1 of the HLM expression in Equation 20, become outcome variables in Level-2 of the HLM measurement model. That is:

$$\begin{aligned} \pi_{0j} &= \beta_{00} + \beta_{01} X_{ij} + r_{0j}, \\ \pi_{1j} &= \beta_{10} + \beta_{11} X_{ij} + r_{1j}, \end{aligned} \tag{21}$$

where:

β_{00}, β_{10}: are the intercepts of the individual effect π_{ij};

X_{ij}: is the Level-2 predictor (group-level explanatory variable);

β_{01}, β_{11}: are the Level-2 coefficients that indicate the direction and strength of association between the Level-2 predictor, X_{ij}, and π_{ij};

r_{0j}, r_{1j}: are the Level-2 random errors that represent the deviation of group j's Level-1 coefficient, π_{ij}, from its predicted value based on the Level-2 model, such that: $r_{ij} \sim N(0, \sigma_r^2)$ and $Cov(r_{ij}, e_{ij}) = 0$ for all i and j.

By substitution of the expression from Equation 21 into Equation 20, the full model may be written out as:

$$\begin{aligned}
Y_{ij} &= (\beta_{00} + \beta_{01}X_{ij} + r_{0j}) + (\beta_{10} + \beta_{11}X_{ij} + r_{1j})A_{ij} + e_{ij} \\
&= \beta_{00} + \beta_{01}X_{ij} + r_{0j} + \beta_{10}A_{ij} + \beta_{11}X_{ij}A_{ij} + r_{1j}A_{ij} + e_{ij} \\
&= \beta_{00} + \beta_{01}X_{ij} + r_{0j} + \beta_{10}A_{ij} + \beta_{11}X_{ij}A_{ij} + r_{1j}A_{ij} + e_{ij} \\
&= \beta_{00} + \beta_{01}X_{ij} + \beta_{10}A_{ij} + \beta_{11}X_{ij}A_{ij} + r_{1j}A_{ij} + r_{0j} + e_{ij}.
\end{aligned}$$

Thus, the Level-2 HLM combined measurement model for one individual predictor on Level-1 and one group predictor on Level-2 is

$$Y_{ij} = \beta_{00} + \beta_{01}X_{ij} + \beta_{10}A_{ij} + \beta_{11}X_{ij}A_{ij} + r_{1j}A_{ij} + r_{0j} + e_{ij}. \tag{22}$$

For a Level-2 HLM analysis, the proportion of variance within individual-level is

equivalent to

$$ICC2_1 = \frac{\sigma_e^2}{\sigma_e^2 + \sigma_r^2}. \tag{23}$$

The proportion of variance within group-level is equivalent to

$$ICC2_2 = \frac{\sigma_r^2}{\sigma_e^2 + \sigma_r^2}.$$

Level-2 Derived Variance.

For a Level-2 HLM,

$$\mathbf{Y}_{N\times 1} = \mathbf{M}_{N\times p}\beta_{p\times 1} + \varepsilon_{N\times 1}$$

where:

N is the total sample size, $N = ng$, for number of Level-1 individuals, n, and the number of Level-2 groups, g;

p is the number of the Level-2 coefficients ($\beta_{00}, \beta_{01}, \beta_{10}$, and β_{11}).

This implies:

$$\begin{bmatrix} Y_{11} \\ Y_{21} \\ Y_{31} \\ \vdots \\ Y_{n-1g} \\ Y_{ng} \end{bmatrix} = \begin{bmatrix} 1 & A_{11} & X_{11} & A_{11}X_{11} \\ 1 & A_{21} & X_{21} & A_{21}X_{21} \\ 1 & A_{31} & X_{31} & A_{31}X_{31} \\ \vdots & \vdots & \vdots & \vdots \\ 1 & A_{n-1g} & X_{n-1g} & A_{n-1g}X_{n-1g} \\ 1 & A_{ng} & X_{ng} & A_{ng}X_{ng} \end{bmatrix} \begin{bmatrix} \beta_{00} \\ \beta_{10} \\ \beta_{01} \\ \beta_{11} \end{bmatrix} + \begin{bmatrix} r_{01} + r_{11}A_{11} + e_{11} \\ r_{01} + r_{11}A_{21} + e_{21} \\ r_{01} + r_{11}A_{31} + e_{31} \\ \vdots \\ r_{0g} + r_{1g}A_{n-1g} + e_{n-1g} \\ r_{0g} + r_{1g}A_{ng} + e_{ng} \end{bmatrix}$$

For $\mathbf{Y} = [Y_{11}, Y_{21}, ..., Y_{ng}]'$ and $Y_{ij} \sim N(\mathbf{M}_{Level-2}\beta, \mathbf{\Sigma})$. Recall, A_{ij} and X_{ij} are independent, $A_{ij} \sim N(0, \sigma_A^2)$, and $X_{ij} \sim N(0, \sigma_X^2)$. This implies:

$$\Sigma_{ij} = Var(Y_{ij})$$

$$
\begin{aligned}
&= Var(\beta_{00} + \beta_{01}X_{ij} + \beta_{10}A_{ij} + \beta_{11}A_{ij}X_{ij} + r_{0j} + r_{1j}A_{ij} + e_{ij}) \\
&= Var(\beta_{00}) + Var(\beta_{01}X_{ij}) + Var(\beta_{10}A_{ij}) + Var(\beta_{11}A_{ij}X_{ij}) \\
&+ Var(r_{0j}) + Var(r_{1j}A_{ij}) + Var(e_{ij}) \\
&= Var(\beta_{00}) + \beta_{01}^2 Var(X_{ij}) + \beta_{10}^2 Var(A_{ij}) + \beta_{11}^2 Var(A_{ij}X_{ij}) \\
&+ Var(r_{0j}) + Var(r_{1j}A_{ij}) + Var(e_{ij}) \\
&= 0 + \beta_{01}^2\sigma_X^2 + \beta_{10}^2\sigma_A^2 + \beta_{11}^2\sigma_A^2\sigma_X^2 + \sigma_r^2 + \sigma_r^2\sigma_A^2 + \sigma_e^2 \\
&= \beta_{01}^2\sigma_X^2 + \beta_{10}^2\sigma_A^2 + \beta_{11}^2\sigma_A^2\sigma_X^2 + \sigma_r^2 + \sigma_r^2\sigma_A^2 + \sigma_e^2 \\
&= \sigma_{Level-2}^2,
\end{aligned}
$$

such that $\Sigma = \sigma_{Level-2}^2 \mathbf{I}_{N\times N}$,

$$
= \begin{bmatrix}
\beta_{01}^2\sigma_X^2 + ... + \sigma_e^2 & 0 & 0 & \dots & 0 \\
0 & \beta_{01}^2\sigma_X^2 + ... + \sigma_e^2 & 0 & \dots & 0 \\
0 & 0 & \beta_{01}^2\sigma_X^2 + ... + \sigma_e^2 & \dots & 0 \\
0 & 0 & 0 & \ddots & 0 \\
0 & 0 & 0 & \dots & \beta_{01}^2\sigma_X^2 + ... + \sigma_e^2
\end{bmatrix}.
$$

For the standard errors of the model coefficients, consider $\mathbf{D}_{Level-2} = \mathbf{M}'_{Level-2}\mathbf{M}_{Level-2}$. Then

$$
\mathbf{D}_{Level-2} = \begin{bmatrix}
1 & 1 & 1 & \dots & 1 \\
A_{11} & A_{21} & A_{31} & \dots & A_{ng} \\
X_{11} & X_{21} & X_{31} & \dots & X_{ng} \\
A_{11}X_{11} & A_{21}X_{21} & A_{31}X_{31} & \dots & A_{ng}X_{ng}
\end{bmatrix}
\begin{bmatrix}
1 & A_{11} & X_{11} & A_{11}X_{11} \\
1 & A_{21} & X_{21} & A_{21}X_{21} \\
1 & A_{31} & X_{31} & A_{31}X_{31} \\
\vdots & \vdots & \vdots & \vdots \\
1 & A_{ng} & X_{ng} & A_{ng}X_{ng}
\end{bmatrix}
$$

$$= \begin{bmatrix} \sum_{k=1}^{f}\sum_{j=1}^{g}\sum_{i=1}^{n} 1 & \sum_{j=1}^{g}\sum_{i=1}^{n} A_{ij} & \sum_{j=1}^{g}\sum_{i=1}^{n} X_{ij} & \sum_{j=1}^{g}\sum_{i=1}^{n} A_{ij}X_{ij} \\ \sum_{j=1}^{g}\sum_{i=1}^{n} A_{ij} & \sum_{j=1}^{g}\sum_{i=1}^{n} A_{ij}^2 & \sum_{j=1}^{g}\sum_{i=1}^{n} A_{ij}X_{ij} & \sum_{j=1}^{g}\sum_{i=1}^{n} A_{ij}^2X_{ij} \\ \sum_{j=1}^{g}\sum_{i=1}^{n} X_{ij} & \sum_{j=1}^{g}\sum_{i=1}^{n} A_{ij}X_{ij} & \sum_{j=1}^{g}\sum_{i=1}^{n} X_{ij}^2 & \sum_{j=1}^{g}\sum_{i=1}^{n} A_{ij}X_{ij}^2 \\ \sum_{j=1}^{g}\sum_{i=1}^{n} A_{ij}X_{ij} & \sum_{j=1}^{g}\sum_{i=1}^{n} A_{ij}^2X_{ij} & \sum_{j=1}^{g}\sum_{i=1}^{n} A_{ij}X_{ij}^2 & \sum_{j=1}^{g}\sum_{i=1}^{n} (A_{ij}X_{ij})^2 \end{bmatrix}$$

$$= \begin{bmatrix} d_{1,1} & d_{1,2} & d_{1,3} & d_{1,4} \\ d_{2,1} & d_{2,2} & d_{2,3} & d_{2,4} \\ d_{3,1} & d_{3,2} & d_{3,3} & d_{3,4} \\ d_{4,1} & d_{4,2} & d_{4,3} & d_{4,4} \end{bmatrix}$$

The standard error of each parameter $\hat{\beta}_{\mathbf{ij}}$ are the analogous diagonal elements derived in Appendix A. That is, generally $s.e.(\mu) = \sqrt{\mathbf{\Sigma}(\mathbf{M'M})^{-\mathbf{1}}}$ (Appendix A). Therefore, for a Level-2 HLM $s.e.(\hat{\beta}) = \sqrt{\sigma^2_{Level-2}\mathbf{I}_{N\times N}\mathbf{D}^{-1}_{Level-2}}$. If the Level-2 HLM predictors have the following distributions $A_{ij} \sim N(0, \sigma_A^2)$ and $X_{ij} \sim N(0, \sigma_X^2)$, then the elements of $\mathbf{D}_{Level-2}$ are:

$$d_{1,1} = \sum_{j=1}^{g}\sum_{i=1}^{n} 1 = ng = N,$$

$$d_{1,2} = a_{2,1} = \sum_{j=1}^{g}\sum_{i=1}^{n} A_{ij} = ngE[A_{ij}] = N\mu_A = N(0) = 0,$$

$$d_{1,3} = a_{3,1} = \sum_{j=1}^{g}\sum_{i=1}^{n} X_{ij} = ngE[X_{ij}] = N\mu_X = N(0) = 0,$$

$$d_{1,4} = a_{2,3} = a_{3,2} = a_{4,1} = \sum_{j=1}^{g}\sum_{i=1}^{n} A_{ij}X_{ij} = ngE[A_{ij}X_{ij}] = N(cov(A_{ij}, X_{ij}) + E[A_{ij}]E[X_{ij}])$$

$$= N(0 + \mu_A\mu_X) = N(0 + (0)(0)) = N(0) = 0,$$

$$d_{2,2} = \sum_{j=1}^{g}\sum_{i=1}^{n} A_{ij}^2 = ngE[A_{ij}^2] = ng(\sigma_A^2 + \mu_A^2) = N(\sigma_A^2 + 0) = N\sigma_A^2,$$

$$d_{2,4} = a_{4,2} = \sum_{j=1}^{g}\sum_{i=1}^{n} X_{ij}^2A_{ij} = ngE[X_{ij}^2A_{ij}] = N(cov(X_{ij}^2, A_{ij}) + E[X_{ij}]^2]E[A_{ij}])$$

$$= N(cov(X_{ij}^2, A_{ij}) + (\sigma_X^2 + E[X_{ij}]^2)E[A_{ij}]) = N(0 + (\sigma_X^2 + \mu_X^2)(\mu_A))$$

$$= N((\sigma_X^2 + 0)(0)) = 0,$$

$$d_{3,3} = \sum_{j=1}^{g}\sum_{i=1}^{n} X_{ij}^2 = ngE[X_{ij}^2] = ng(\sigma_X^2 + \mu_X^2) = N(\sigma_X^2 + 0) = N\sigma_X^2,$$

$$d_{3,4} = a_{4,3} = \sum_{j=1}^{g}\sum_{i=1}^{n} X_{ij}A_{ij}^2 = ngE[X_{ij}A_{ij}^2] = N(cov(X_{ij}, A_{ij}^2) + E[X_{ij}]]E[A_{ij}^2])$$

$$= N(cov(X_{ij}, A_{ij}^2) + E[X_{ij}](\sigma_A^2 + E[A_{ij}]^2)) = N(0 + (\mu_X)(\sigma_A^2 + \mu_A^2))$$

$$= N((\sigma_A^2 + 0)(0)) = 0,$$

$$d_{4,4} = \sum_{j=1}^{g}\sum_{i=1}^{n} (X_{ijkl}A_{ij})^2 = ngE[X_{ij}^2 A_{ij}^2] = N(cov(X_{ij}^2, A_{ij}^2) + E[X_{ij}^2]]E[A_{ij}^2])$$

$$= N(cov(X_{ij}^2, A_{ij}^2) + (\sigma_X^2 + E[X_{ij}]^2)(\sigma_A^2 + E[A_{ij}]^2)) = N(\sigma_X^2 + \mu_X^2)(\sigma_A^2 + \mu_A^2)$$

$$= N(\sigma_X^2 + 0)(\sigma_A^2 + 0) = N\sigma_X^2\sigma_A^2.$$

Hence by substitution, this implies

$$\mathbf{D}_{Level-2} = \begin{bmatrix} N & 0 & 0 & 0 \\ 0 & N\sigma_X^2 & 0 & 0 \\ 0 & 0 & N\sigma_A^2 & 0 \\ 0 & 0 & 0 & N\sigma_A^2\sigma_X^2 \end{bmatrix}.$$

The inverse of the diagonal matrix $\mathbf{D}_{Level-2}$, is denoted $\mathbf{D^{-1}}_{Level-2}$ and equivalent to

$$\mathbf{D}_{Level-2}^{-1} = \begin{bmatrix} \frac{1}{N} & 0 & 0 & 0 \\ 0 & \frac{1}{N\sigma_X^2} & 0 & 0 \\ 0 & 0 & \frac{1}{N\sigma_A^2} & 0 \\ 0 & 0 & 0 & \frac{1}{N\sigma_A^2\sigma_X^2} \end{bmatrix}.$$

By Appendix A, $Var(\hat{\beta}) = \sigma^2_{Level-2}\mathbf{I}_{N\times N}\mathbf{D}^{-1}_{Level-2}$. Therefore,

$$Var(\hat{\beta}) = \begin{bmatrix} \frac{\sigma^2_{Level-2}}{N} & 0 & 0 & 0 \\ 0 & \frac{\sigma^2_{Level-2}}{N\sigma^2_X} & 0 & 0 \\ 0 & 0 & \frac{\sigma^2_{Level-2}}{N\sigma^2_A} & 0 \\ 0 & 0 & 0 & \frac{\sigma^2_{Level-2}}{N\sigma^2_A\sigma^2_X} \end{bmatrix}.$$

Hence, $s.e.(\hat{\beta}) = \sqrt{\sigma^2_{Level-2}\mathbf{I}_{N\times N}\mathbf{D}^{-1}_{Level-2}}$. Thus,

$$s.e.(\hat{\beta}) = \begin{bmatrix} \sqrt{\frac{\sigma^2_{Level-2}}{N}} & 0 & 0 & 0 \\ 0 & \sqrt{\frac{\sigma^2_{Level-2}}{N\sigma^2_X}} & 0 & 0 \\ 0 & 0 & \sqrt{\frac{\sigma^2_{Level-2}}{N\sigma^2_A}} & 0 \\ 0 & 0 & 0 & \sqrt{\frac{\sigma^2_{Level-2}}{N\sigma^2_A\sigma^2_X}} \end{bmatrix}. \tag{24}$$

Level-3 of the HLM Measurement Model for 1 Individual Predictor at Level-1, 1 Group Predictor at Level-2, and 1 Unit Predictor at Level-3.

For Figure 9, the Level-2 coefficients with Level-3 indexing ($\beta_{00k}, \beta_{01k}, \beta_{10k}$, and β_{11k}) defined in Level-2 of the HLM expressed in Equation 22, become outcome variables in Level-3 of the HLM measurement model such that $k = 1, ..., h$. That is:

$$\begin{aligned} \beta_{00k} &= \gamma_{000} + \gamma_{001}W_{ijk} + u_{00k}, \\ \beta_{01k} &= \gamma_{010} + \gamma_{011}W_{ijk} + u_{01k}, \\ \beta_{10k} &= \gamma_{100} + \gamma_{101}W_{ijk} + u_{10k}, \\ \beta_{11k} &= \gamma_{110} + \gamma_{111}W_{ijk} + u_{11k}, \end{aligned} \tag{25}$$

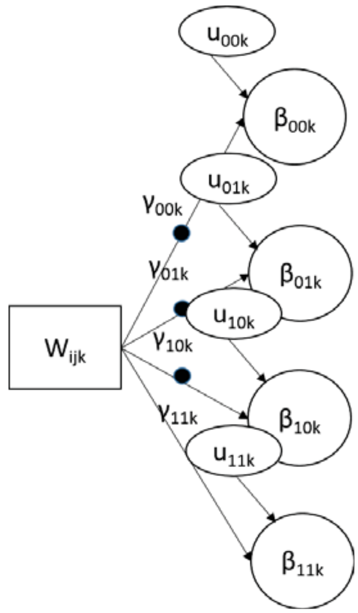

Figure 9. Third level of an HLM structural model with 1 unit predictor at Level-3.

where:

γ_{000},γ_{010},γ_{100},γ_{110}: are the intercepts of the unit effect in modeling the group effect β_{ijk};

W_{ijk}: is the Level-3 predictor (unit-level explanatory variable);

γ_{001},γ_{011},γ_{101},γ_{111}: are the Level-3 coefficients that indicate the direction and strength of association between the Level-3 predictor, W_{ijk}, and the β_{ijk};

u_{00k},u_{01k},u_{00k},u_{01k}: are the Level-3 random errors that represent the deviation of unit k's Level-2 coefficient, β_{ijk}, from its predicted value based on the Level-3 model, such that: $u_{ijk} \sim N(0, \sigma_u^2)$ and $Cov(u_{ijk}, r_{ijk}) = Cov(u_{ijk}, e_{ijk}) = Cov(r_{ijk}, e_{ijk}) = 0$ for all i, j, and k.

By substitution of the expression from Equation 25 into Equation 22, the full

model may be written out as:

$$
\begin{aligned}
Y_{ijk} &= (\gamma_{000} + \gamma_{001}W_{ijk} + u_{00k}) + (\gamma_{010} + \gamma_{011}W_{ijk} + u_{01k})X_{ijk} \\
&+ (\gamma_{100} + \gamma_{101}W_{ijk} + u_{10k})A_{ijk} + (\gamma_{110} + \gamma_{111}W_{ijk} + u_{11k})X_{ijk}A_{ijk} \\
&+ r_{0jk} + r_{1jk}A_{ijk} + e_{ijk} \\
&= \gamma_{000} + \gamma_{001}W_{ijk} + u_{00k} + \gamma_{010}X_{ijk} + \gamma_{011}W_{ijk}X_{ijk} + u_{01k}X_{ijk} \\
&+ \gamma_{100}A_{ijk} + \gamma_{101}W_{ijk}A_{ijk} + u_{10k}A_{ijk} + \gamma_{110}X_{ijk}A_{ijk} \\
&+ \gamma_{111}W_{ijk}X_{ijk}A_{ijk} + u_{11k}X_{ijk}A_{ijk} + r_{0jk} + r_{1jk}A_{ijk} + e_{ijk} \\
&= \gamma_{000} + \gamma_{001}W_{ijk} + \gamma_{010}X_{ijk} + \gamma_{011}W_{ijk}X_{ijk} \\
&+ A_{ijk}(\gamma_{100} + \gamma_{101}W_{ijk} + u_{10k} + r_{1jk} + X_{ijk}(u_{11k} + \gamma_{110} + \gamma_{111}W_{ijk})) \\
&+ u_{00k} + u_{01k}X_{ijk} + r_{0jk} + e_{ijk}.
\end{aligned}
$$

Thus, the Level-3 HLM combined measurement model for one individual predictor on Level-1, one group predictor on Level-2, and one unit predictor on Level-3 is

$$
\begin{aligned}
Y_{ijk} &= \gamma_{000} + \gamma_{010}X_{ijk} + \gamma_{001}W_{ijk} + \gamma_{011}X_{ijk}W_{ijk} + \gamma_{100}A_{ijk} \\
&+ \gamma_{101}A_{ijk}W_{ijk} + \gamma_{110}A_{ijk}X_{ijk} + \gamma_{111}A_{ijk}X_{ijk}W_{ijk} + u_{11k}A_{ijk}X_{ijk} \\
&+ u_{00k} + u_{01k}X_{ijk} + u_{10k}A_{ijk} + r_{1jk}A_{ijk} + r_{0jk} + e_{ijk}.
\end{aligned} \tag{26}
$$

For a Level-3 HLM analysis, the proportion of variance of individuals is

$$ICC3_1 = \frac{\sigma_e^2}{\sigma_e^2 + \sigma_r^2 + \sigma_u^2}.$$

The proportion of variance among groups is

$$ICC3_2 = \frac{\sigma_r^2}{\sigma_e^2 + \sigma_r^2 + \sigma_u^2}.$$

The proportion of variance of the units is

$$ICC3_3 = \frac{\sigma_u^2}{\sigma_e^2 + \sigma_r^2 + \sigma_u^2}.$$

Level-3 Derived Variance.

For a Level-3 HLM,

$$\mathbf{Y}_{N\times 1} = \mathbf{M}_{N\times p}\gamma_{p\times 1} + \varepsilon_{N\times 1}$$

where:

N is the total sample size, $N = ngh$, for the number of Level-1 individuals, n, the number of Level-2 groups, g, and the number of Level-3 units, h;

p is the number of the Level-3 coefficients ($\gamma_{000}, \gamma_{100}, \gamma_{010}$, γ_{001}, γ_{110}, γ_{101}, γ_{011}, and γ_{111}).

This implies:

$$
\begin{bmatrix} Y_{111} \\ Y_{112} \\ \vdots \\ Y_{11h} \\ Y_{121} \\ \vdots \\ Y_{12h} \\ \vdots \\ Y_{1g1} \\ \vdots \\ Y_{1gh} \\ \vdots \\ Y_{ngh} \end{bmatrix}
=
\begin{bmatrix}
1 & A_{111} & X_{111} & W_{111} & A_{111}X_{111} & A_{111}W_{111} & X_{111}W_{111} & A_{111}X_{111}W_{111} \\
1 & A_{211} & X_{211} & W_{211} & A_{211}X_{211} & A_{211}W_{211} & X_{211}W_{211} & A_{211}X_{211}W_{211} \\
1 & A_{311} & X_{311} & W_{311} & A_{311}X_{311} & A_{311}W_{311} & X_{311}W_{311} & A_{311}X_{311}W_{311} \\
 & & & & \vdots & & & \\
1 & A_{n-1gh} & X_{n-1gh} & W_{n-1gh} & A_{n-1gh}X_{n-1gh} & A_{n-1gh}W_{n-1gh} & X_{n-1gh}W_{n-1gh} & A_{n-1gh}X_{n-1gh}W_{n-1gh} \\
1 & A_{ngh} & X_{ngh} & W_{11h} & A_{ngh}X_{ngh} & A_{ngh}W_{ngh} & X_{ngh}W_{ngh} & A_{ngh}X_{ngh}W_{ngh}
\end{bmatrix}
\begin{bmatrix} \gamma_{000} \\ \gamma_{100} \\ \gamma_{010} \\ \gamma_{001} \\ \gamma_{110} \\ \gamma_{101} \\ \gamma_{011} \\ \gamma_{111} \end{bmatrix}
$$

$$
+ \begin{bmatrix}
u_{101}A_{111} + u_{011}X_{111} + u_{111}A_{111}X_{111} + r_{111}A_{111} + u_{001} + r_{011} + e_{111} \\
u_{101}A_{211} + u_{011}X_{211} + u_{111}A_{211}X_{112} + r_{111}A_{211} + u_{001} + r_{011} + e_{211} \\
u_{111}A_{311} + u_{011}X_{311} + u_{111}A_{311}X_{11h} + r_{111}A_{h11} + u_{001} + r_{011} + e_{311} \\
\vdots \\
u_{10h}A_{n-1gh} + u_{01h}X_{n-1gh} + u_{11h}A_{n-1gh}X_{n-1gh} + r_{11h}A_{n-1gh} + u_{00h} + r_{0gh} + e_{n-1gh} \\
u_{10h}A_{ngh} + u_{01h}X_{ngh} + u_{11h}A_{ngh}X_{ngh} + r_{11h}A_{ngh} + u_{00h} + r_{0gh} + e_{ngh}
\end{bmatrix}.
$$

For $\mathbf{Y} = [Y_{111}, Y_{211}, ..., Y_{ngh}]'$ and $Y_{ijk} \sim N(\mathbf{M}_{Level-3}\gamma, \mathbf{\Sigma})$. Recall, A_{ijk}, X_{ijk}, and W_{ijk} are independent, $A_{ijk} \sim N(0, \sigma_A^2)$, $X_{ijk} \sim N(0, \sigma_X^2)$, and $W_{ijk} \sim N(0, \sigma_W^2)$. Therefore,

$$
\begin{aligned}
\Sigma_{ijk} &= Var(Y_{ijk}) \\
&= Var(\gamma_{000} + \gamma_{011}X_{ijk} + \gamma_{001}W_{ijk} + \gamma_{011}X_{ijk}W_{ijk} + \gamma_{100}A_{ijk} \\
&+ \gamma_{101}A_{ijk}W_{ijk} + \gamma_{110}A_{ijk}X_{ijk} + \gamma_{111}A_{ijk}X_{ijk}W_{ijk} + u_{11k}A_{ijk}X_{ijk} \\
&+ u_{00k} + u_{01k}X_{ijk} + u_{10k}A_{ijk} + r_{1jk}A_{ijk} + r_{0jk} + e_{ijk}) \\
&= Var(\gamma_{000}) + Var(\gamma_{011}X_{ijk}) + Var(\gamma_{001}W_{ijk}) + Var(\gamma_{011}X_{ijk}W_{ijk}) + Var(\gamma_{100}A_{ijk}) \\
&+ Var(\gamma_{101}A_{ijk}W_{ijk}) + Var(\gamma_{110}A_{ijk}X_{ijk}) + Var(\gamma_{111}A_{ijk}X_{1jk}W_{ijk}) \\
&+ Var(u_{11k}A_{ijk}X_{ijk}) + Var(u_{00k}) + Var(u_{01k}X_{1jk}) + Var(u_{10k}A_{ijk}) + Var(r_{1jk}A_{ijk}) \\
&+ Var(r_{0jk}) + Var(e_{ijk}) \\
&= 0 + \gamma_{010}^2\sigma_X^2 + \gamma_{001}^2\sigma_W^2 + \gamma_{011}^2\sigma_X^2\sigma_W^2 + \gamma_{100}^2\sigma_A^2 + \gamma_{101}^2\sigma_A^2\sigma_W^2 + \gamma_{110}^2\sigma_A^2\sigma_X^2 + \gamma_{111}^2\sigma_A^2\sigma_X^2\sigma_W^2 \\
&+ \sigma_u^2\sigma_A^2\sigma_X^2 + \sigma_u^2 + \sigma_u^2\sigma_X^2 + \sigma_u^2\sigma_A^2 + \sigma_r^2\sigma_A^2 + \sigma_r^2 + \sigma_e^2 \\
&= \gamma_{010}^2\sigma_X^2 + \gamma_{001}^2\sigma_W^2 + \gamma_{011}^2\sigma_X^2\sigma_W^2 + \gamma_{100}^2\sigma_A^2 + \gamma_{101}^2\sigma_A^2\sigma_W^2 + \gamma_{110}^2\sigma_A^2\sigma_X^2 + \gamma_{111}^2\sigma_A^2\sigma_X^2\sigma_W^2 \\
&+ \sigma_u^2\sigma_A^2\sigma_X^2 + \sigma_u^2 + \sigma_u^2\sigma_X^2 + \sigma_u^2\sigma_A^2 + \sigma_r^2\sigma_A^2 + \sigma_r^2 + \sigma_e^2 \\
&= \sigma_{Level-3}^2
\end{aligned}
$$

such that

$$\mathbf{\Sigma} = \sigma_{Level-3}^2\mathbf{I}_{N\times N},$$

$$
= \begin{bmatrix}
\gamma_{010}^2\sigma_X^2 + \gamma_{001}^2\sigma_W^2 + ... & 0 & \cdots & 0 \\
+\sigma_u^2\sigma_A^2 + \sigma_r^2\sigma_A^2 + \sigma_r^2 + \sigma_e^2 & & & \\
0 & \gamma_{010}^2\sigma_X^2 + \gamma_{001}^2\sigma_W^2 + ... & \cdots & 0 \\
 & +\sigma_u^2\sigma_A^2 + \sigma_r^2\sigma_A^2 + \sigma_r^2 + \sigma_e^2 & & \\
0 & 0 & \ddots & 0 \\
0 & 0 & & \gamma_{010}^2\sigma_X^2 + \gamma_{001}^2\sigma_W^2 + ... \\
 & & & +\sigma_u^2\sigma_A^2 + \sigma_r^2\sigma_A^2 + \sigma_r^2 + \sigma_e^2
\end{bmatrix}.
$$

For the standard errors of the model coefficients, consider

$\mathbf{D}_{Level-3} = \mathbf{M}'_{Level-3}\mathbf{M}_{Level-3}$. Then

$\mathbf{D}_{Level-3} =$

$$
\begin{bmatrix}
1 & 1 & \cdots & 1 \\
A_{111} & A_{112} & \cdots & A_{ngh} \\
X_{.11} & X_{.12} & \cdots & X_{.gh} \\
W_{..1} & W_{..2} & \cdots & W_{..h} \\
\vdots & \vdots & \cdots & \vdots \\
A_{111}X_{.11}W_{..1} & A_{112}X_{.12}W_{..2} & \cdots & A_{ngh}X_{.gh}W_{..h}
\end{bmatrix}
\begin{bmatrix}

$$d_{8,8} = \sum_{k=1}^{h}\sum_{j=1}^{g}\sum_{i=1}^{n}(A_{ijk}X_{ijk}W_{ijk})^2.$$

The standard error of each parameter $\hat{\gamma}_{\mathbf{ijk}}$ are the analogous diagonal elements derived in Appendix A. That is, generally $s.e.(\mu) = \sqrt{\mathbf{\Sigma(M'M)^{-1}}}$ (Appendix A). Therefore, for a Level-3 HLM $s.e.(\hat{\gamma}) = \sqrt{\sigma^2_{Level-3}\mathbf{I}_{NxN}\mathbf{D}^{-1}_{Level-3}}$. If the Level-3 HLM predictors have the following distributions $A_{ijk} \sim N(0, \sigma_A^2)$, $X_{ijk} \sim N(0, \sigma_X^2)$, and $W_{ijk} \sim N(0, \sigma_W^2)$, then the elements of $\mathbf{D}_{Level-3}$ are:

$$d_{1,1} = \sum_{k=1}^{h}\sum_{j=1}^{g}\sum_{i=1}^{n} 1 = ngh = N,$$

$$d_{1,2} = d_{2,1} = \sum_{k=1}^{h}\sum_{j=1}^{g}\sum_{i=1}^{n} A_{ijk} = nghE[A_{ijk}] = N\mu_A = N(0) = 0,$$

$$d_{1,3} = d_{3,1} = \sum_{k=1}^{h}\sum_{j=1}^{g}\sum_{i=1}^{n} X_{ijk} = nghE[X_{ijk}] = N\mu_X = N(0) = 0,$$

$$d_{1,4} = d_{4,1} = \sum_{k=1}^{h}\sum_{j=1}^{g}\sum_{i=1}^{n} W_{ijk} = nghE[W_{ijk}] = N\mu_W = N(0) = 0,$$

$$d_{1,5} = d_{2,3} = d_{3,2} = d_{5,1} = \sum_{k=1}^{h}\sum_{j=1}^{g}\sum_{i=1}^{n} A_{ijk}X_{ijk} = nghE[A_{ijk}X_{ijk}]$$

$$= N(0 + (0 + (\sigma_X^2 + 0)0)(\sigma_W^2 + 0)) = 0,$$

$$d_{7,7} = \sum_{k=1}^{h}\sum_{j=1}^{g}\sum_{i=1}^{n}(X_{ijk}W_{ijk})^2 = nghE[X_{ijk}^2 W_{ijk}^2]$$

$$= N(cov(X_{ijk}^2, W_{ijk}^2) + E[X_{ijk}^2]E[X_{ijk}^2] = N(0 + (\sigma_X^2 + \mu_X^2)(\sigma_W^2 + \mu_W^2))$$

$$= N(0 + (\sigma_X^2 + 0)(\sigma_W^2 + 0)) = N\sigma_X^2\sigma_W^2,$$

$$d_{7,8} = \sum_{k=1}^{h}\sum_{j=1}^{g}\sum_{i=1}^{n} A_{ijk}X_{ijk}^2 W_{ijk}^2 = nghE[A_{ijk}X_{ijk}^2 W_{ijk}^2]$$

$$= N(cov(A_{ijk}X_{ijk}^2, W_{ijk}^2) + E[A_{ijk}X_{ijk}^2]E[W_{ijk}^2])$$

$$= N(0 + (cov(A_{ijk}, X_{ijk}^2) + E[A_{ijk}]E[X_{ijk}^2])(\sigma_W^2 + \mu_W^2))$$

$$= N(0 + (0 + \mu_A(\sigma_X^2 + \mu_X^2))(\sigma_W^2 + \mu_W^2))$$

$$= N(0 + (0 + 0(\sigma_X^2 + 0))(\sigma_W^2 + 0)) = 0,$$

$$d_{8,8} = \sum_{k=1}^{h}\sum_{j=1}^{g}\sum_{i=1}^{n}(A_{ijk}X_{ijk}W_{ijk})^2 = nghE[A_{ijk}^2X_{ijk}^2W_{ijk}^2]$$

$$= N(cov(A_{ijk}^2X_{ijk}^2, W_{ijk}^2) + E[A_{ijk}^2X_{ijk}^2]E[W_{ijk}^2])$$

$$= N(0 + (cov(A_{ijk}^2, X_{ijk}^2) + E[A_{ijk}^2]E[X_{ijk}^2])(\sigma_W^2 + \mu_W^2))$$

$$= N(0 + (0 + (\sigma_A^2 + \mu_A^2)(\sigma_X^2 + \mu_X^2))(\sigma_W^2 + \mu_W^2))$$

$$= N(0 + (0 + (\sigma_A^2 + 0)(\sigma_X^2 + 0))(\sigma_W^2 + 0)) = N\sigma_A^2\sigma_X^2\sigma_W^2.$$

Hence by substitution, this implies

$$\mathbf{D}_{Level-3} = \begin{bmatrix} N & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & N\sigma_A^2 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & N\sigma_X^2 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & N\sigma_W^2 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & N\sigma_A^2\sigma_X^2 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & N\sigma_A^2\sigma_W^2 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & N\sigma_X^2\sigma_W^2 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & N\sigma_A^2\sigma_X^2\sigma_W^2 \end{bmatrix}.$$

The inverse of the diagonal matrix $\mathbf{D}_{Level-3}$ is denoted $\mathbf{D}_{Level-3}^{-1}$ and is equivalent to

$$\mathbf{D}_{Level-3}^{-1} = \begin{bmatrix} \frac{1}{N} & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & \frac{1}{N\sigma_A^2} & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & \frac{1}{N\sigma_X^2} & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & \frac{1}{N\sigma_W^2} & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & \frac{1}{N\sigma_A^2\sigma_X^2} & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & \frac{1}{N\sigma_A^2\sigma_W^2} & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & \frac{1}{N\sigma_X^2\sigma_W^2} & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & \frac{1}{N\sigma_A^2\sigma_X^2\sigma_W^2} \end{bmatrix}.$$

By Appendix A, $Var(\hat{\gamma}) = \sigma_{Level-3}^2 \mathbf{I}_{N\times N} \mathbf{D}_{Level-3}^{-1}$. Therefore,

$$Var(\hat{\gamma}) = \begin{bmatrix} \frac{\sigma_{Level-3}^2}{N} & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & \frac{\sigma_{Level-3}^2}{N\sigma_A^2} & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & \frac{\sigma_{Level-3}^2}{N\sigma_X^2} & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & \frac{\sigma_{Level-3}^2}{N\sigma_W^2} & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & \frac{\sigma_{Level-3}^2}{N\sigma_A^2\sigma_X^2} & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & \frac{\sigma_{Level-3}^2}{N\sigma_A^2\sigma_W^2} & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & \frac{\sigma_{Level-3}^2}{N\sigma_X^2\sigma_W^2} & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & \frac{\sigma_{Level-3}^2}{N\sigma_A^2\sigma_X^2\sigma_W^2} \end{bmatrix}.$$

Hence, $s.e.(\hat{\gamma}) = \sqrt{\sigma^2_{Level-3}\mathbf{I}_{N\times N}\mathbf{D}^{-1}_{Level-3}}$. Thus,

$$s.e.(\hat{\gamma}) = \begin{bmatrix} \sqrt{\frac{\sigma^2_{Level-3}}{N}} & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & \sqrt{\frac{\sigma^2_{Level-3}}{N\sigma^2_A}} & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & \sqrt{\frac{\sigma^2_{Level-3}}{N\sigma^2_X}} & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & \ddots & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & \sqrt{\frac{\sigma^2_{Level-3}}{N\sigma^2_A\sigma^2_W}} & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & \sqrt{\frac{\sigma^2_{Level-3}}{N\sigma^2_X\sigma^2_W}} & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & \sqrt{\frac{\sigma^2_{Level-3}}{N\sigma^2_A\sigma^2_W A}} \end{bmatrix}. \tag{27}$$

Level-4 HLM Measurement Model for 1 Individual Predictor at Level-1, 1 Group Predictor at Level-2, 1 Unit Predictor at Level-3, and 1 Organization Predictor at Level-4.

For Figure 10, the Level-3 coefficients with Level-4 indexing ($\gamma_{000l}, \gamma_{010l}, \gamma_{100l}$, γ_{110l}, $\gamma_{001l}, \gamma_{011l}, \gamma_{101l}$, γ_{111l}), defined in Level-3 of the HLM expressed in Equation 44, become outcome variables in Level-4 of the HLM measurement model such that $l = 1, ..., f$. That is:

$$\begin{aligned} \gamma_{000l} &= \delta_{0000} + \delta_{0001}Z_{ijkl} + v_{000l}, \\ \gamma_{010l} &= \delta_{0100} + \delta_{0101}Z_{ijkl} + v_{010l}, \\ \gamma_{100l} &= \delta_{1000} + \delta_{1001}Z_{ijkl} + v_{100l}, \\ \gamma_{110l} &= \delta_{1100} + \delta_{1101}Z_{ijkl} + v_{110l}, \\ \gamma_{001l} &= \delta_{0010} + \delta_{0011}Z_{ijkl} + v_{001l}, \\ \gamma_{011l} &= \delta_{0110} + \delta_{0111}Z_{ijkl} + v_{011l}, \\ \gamma_{101l} &= \delta_{1010} + \delta_{1011}Z_{ijkl} + v_{101l}, \\ \gamma_{111l} &= \delta_{1110} + \delta_{1111}Z_{ijkl} + v_{111l}, \end{aligned} \tag{28}$$

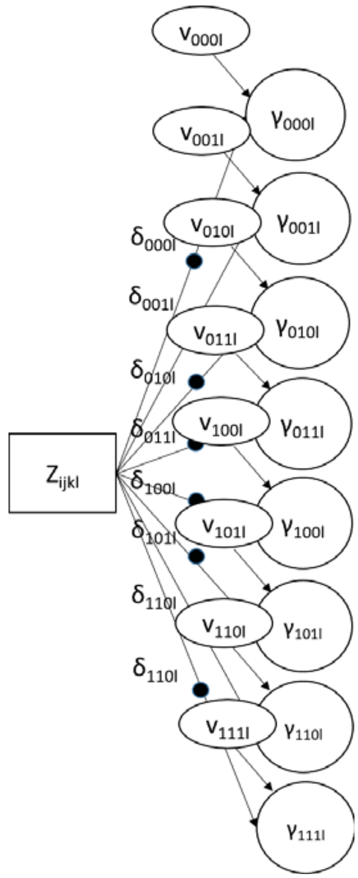

Figure 10. Fourth level of an HLM structural model with 1 organizational predictor at Level-4.

where: δ_{0000},δ_{0100},δ_{1000},δ_{1100},δ_{0010},δ_{0110}, δ_{1010},δ_{1110}: are the intercepts for the organizational effect in modeling the unit effect γ_{ijkl};

Z_{ijkl}: is the Level-4 predictor (organizational-level explanatory variable);

δ_{0001},δ_{0101},δ_{1001},δ_{1101},δ_{0011},δ_{0111},δ_{1011},δ_{1111}: are the Level-4 coefficients that indicate the direction and strength of association between the Level-4 predictor, Z_{ijkl}, and the γ_{ijkl};

v_{000l},v_{010l},v_{100l},v_{110l},v_{001l},v_{001l},v_{101l},v_{111l}: are the Level-4 random errors that represent the deviation of organization $ijkl$'s Level-3 coefficient, γ_{ijkl}, from its predicted value based on the Level-4 model. Such that: $v_{ijkl} \sim N(0, \sigma_v^2)$, $cov(v_{ijkl}, u_{..kl}) = cov(v_{ijkl}, r_{ijkl}) =$

$cov(v_{ijkl}, e_{ijkl}) = cov(u_{ijkl}, r_{ijkl}) = cov(u_{ijkl}, e_{ijkl}) = cov(r_{ijkl}, e_{ijkl}) = 0$ for all i,j,k, and l.

By substitution of the expression from Equation 28 into Equation 44, the full model may be written out as:

$$
\begin{aligned}
Y_{ijkl} = {} & (\delta_{0000} + \delta_{0001}Z_{ijkl} + v_{000l}) + (\delta_{0100} + \delta_{0101}Z_{ijkl} + v_{010l})X_{ijkl} \\
& + (\delta_{0010} + \delta_{0011}Z_{ijkl} + v_{001l})W_{ijkl} + (\delta_{0110} + \delta_{0111}Z_{ijkl} + v_{011l})X_{ijkl}W_{ijkl} \\
& + (\delta_{1000} + \delta_{1001}Z_{ijkl} + v_{100l})A_{.jkl} + (\delta_{1010} + \delta_{1011}Z_{ijkl} + v_{101l})A_{ijkl}W_{ijkl} \\
& + (\delta_{1100} + \delta_{1101}Z_{ijkl} + v_{110l})A_{ijkl}X_{ijkl} + (\delta_{1110} + \delta_{1111}Z_{ijkl} + v_{111l})A_{ijkl}X_{ijkl}W_{ijkl} \\
& + u_{11kl}A_{ijkl}X_{ijkl} + u_{00kl} + u_{01kl}X_{ijkl} + u_{10kl}A_{ijkl} + r_{1jkl}A_{ijkl} + r_{0jkl} + e_{ijkl}
\end{aligned}
$$

$$
\begin{aligned}
= {} & \delta_{0000} + \delta_{0001}Z_{ijkl} + v_{000l} + \delta_{0100}X_{ijkl} + \delta_{0101}X_{ijkl}Z_{ijkl} + v_{010l}X_{ijkl} + \delta_{0010}W_{ijkl} \\
& + \delta_{0011}W_{ijkl}Z_{ijkl} + v_{001l}W_{ijkl} + \delta_{0110}X_{ijkl}W_{ijkl} + \delta_{0111}X_{ijkl}W_{ijkl}Z_{ijkl} + v_{011l}X_{ijkl}W_{ijkl} \\
& + \delta_{1000}A_{ijkl} + \delta_{1001}A_{ijkl}Z_{...} + v_{100l}A_{ijkl} + \delta_{1010}A_{ijkl}W_{ijkl} + \delta_{1011}A_{ijkl}W_{ijkl}Z_{ijkl} \\
& + v_{101l}A_{ijkl}W_{ijkl} + \delta_{1100}A_{ijkl}X_{ijkl} + \delta_{1101}A_{ijkl}X_{ijkl}Z_{ijkl} + v_{110l}A_{ijkl}X_{ijkl} \\
& + \delta_{1110}A_{ijkl}X_{ijkl}W_{ijkl} + \delta_{1111}A_{ijkl}X_{ijkl}W_{ijkl}Z_{ijkl} + v_{111l}A_{ijkl}X_{ijkl}W_{ijkl} \\
& + u_{11kl}A_{ijkl}X_{ijkl} + u_{00kl} + u_{01kl}X_{ijkl} + u_{10kl}A_{ijkl} + r_{1jkl}A_{ijkl} + r_{0jkl} + e_{ijkl}
\end{aligned}
$$

$$
\begin{aligned}
= {} & \delta_{0000} + \delta_{1000}A_{ijkl} + \delta_{0100}X_{ijkl} + \delta_{0010}W_{ijkl} + \delta_{0001}Z_{ijkl} + \delta_{1100}A_{ijkl}X_{ijkl} + \delta_{1010}A_{ijkl}W_{ijkl} \\
& + \delta_{1001}A_{ijkl}Z_{...} + \delta_{0110}X_{ijkl}W_{ijkl} + \delta_{0101}X_{ijkl}Z_{ijkl} + \delta_{0011}W_{ijkl}Z_{ijkl} + \delta_{1110}A_{ijkl}X_{ijkl}W_{ijkl} \\
& + \delta_{1101}A_{ijkl}X_{ijkl}Z_{ijkl} + \delta_{1011}A_{ijkl}W_{ijkl}Z_{ijkl} + \delta_{0111}X_{ijkl}W_{ijkl}Z_{ijkl} + \delta_{1111}A_{ijkl}X_{ijkl}W_{ijkl}Z_{ijkl} \\
& + v_{111l}A_{ijkl}X_{ijkl}W_{ijkl} + v_{011l}X_{ijkl}W_{ijkl} + v_{101l}A_{ijkl}W_{ijkl} + v_{110l}A_{ijkl}X_{ijkl} \\
& + v_{001l}W_{ijkl} + v_{010l}X_{ijkl} + v_{100l}A_{ijkl} + v_{000l} \\
& + u_{11kl}A_{ijkl}X_{ijkl} + u_{00kl} + u_{01kl}X_{ijkl} + u_{10kl}A_{ijkl} + r_{1jkl}A_{ijkl} + r_{0jkl} + e_{ijkl}.
\end{aligned}
$$

Thus the Level-4 HLM combined measurement model for one individual predictor on

Level-1, one group predictor on Level-2, one unit predictor on Level-3 and one organization predictor on Level-4 is

$$\begin{aligned}
Y_{ijkl} = {} & \delta_{0000} + \delta_{1000}A_{ijkl} + \delta_{0100}X_{ijkl} + \delta_{0010}W_{ijkl} + \delta_{0001}Z_{ijkl} + \delta_{1100}A_{ijkl}X_{ijkl} + \delta_{1010}A_{ijkl}W_{ijkl} \\
& + \delta_{1001}A_{ijkl}Z_{ijkl} + \delta_{0110}X_{ijkl}W_{ijkl} + \delta_{0101}X_{ijkl}Z_{ijkl} + \delta_{0011}W_{ijkl}Z_{ijkl} + \delta_{1110}A_{ijkl}X_{ijkl}W_{ijkl} \\
& + \delta_{1101}A_{ijkl}X_{ijkl}Z_{ijkl} + \delta_{1011}A_{ijkl}W_{ijkl}Z_{ijkl} + \delta_{0111}X_{ijkl}W_{ijkl}Z_{ijkl} + \delta_{1111}A_{ijkl}X_{ijkl}W_{ijkl}Z_{ijkl} \\
& + v_{111l}A_{ijkl}X_{ijkl}W_{ijkl} + v_{011l}X_{ijkl}W_{ijkl} + v_{101l}A_{ijkl}W_{ijkl} + v_{110l}A_{ijkl}X_{ijkl} \\
& + v_{001l}W_{ijkl} + v_{010l}X_{ijkl} + v_{100l}A_{ijkl} + v_{000l} \\
& + u_{11kl}A_{ijkl}X_{ijkl} + u_{00kl} + u_{01kl}X_{ijkl} + u_{10kl}A_{ijkl} + r_{1jkl}A_{ijkl} + r_{0jkl} + e_{ijkl}.
\end{aligned} \tag{29}$$

For a Level-4 HLM analysis, the proportion of variance of individuals is

$$ICC_1 = \frac{\sigma_e^2}{\sigma_e^2 + \sigma_r^2 + \sigma_u^2 + \sigma_u^2}.$$

The proportion of variance among groups is

$$ICC_2 = \frac{\sigma_r^2}{\sigma_e^2 + \sigma_r^2 + \sigma_u^2 + \sigma_v^2}.$$

The proportion of variance among units is

$$ICC_3 = \frac{\sigma_r^2}{\sigma_e^2 + \sigma_r^2 + \sigma_u^2 + \sigma_v^2}.$$

The proportion of variance among organizations is

$$ICC_4 = \frac{\sigma_v^2}{\sigma_e^2 + \sigma_r^2 + \sigma_u^2 + \sigma_v^2}.$$

Level-4 Derived Variance.

For a Level-4 HLM,

$$\mathbf{Y}_{N\times 1} = \mathbf{M}_{N\times p}\delta_{p\times 1} + \varepsilon_{N\times 1}$$

where:

N is the total sample size, $N = nghf$, for number of Level-1 individuals, n, the number of Level-2 groups, g, the number of Level-3 units, g, and the number of Level-4 organizations, f;

p is the number of Level-4 coefficients ($\delta_{0000}, \delta_{0001}, \delta_{0010}$, δ_{0011}, δ_{0100}, δ_{0101}, δ_{0110}, δ_{0111}, δ_{1000}, δ_{1001}, δ_{1010}, δ_{1011}, δ_{1100}, δ_{1101}, δ_{1110}, δ_{1111}).

In expanded form, this implies

$$
\begin{bmatrix} Y_{1111} \\ Y_{2111} \\ Y_{3111} \\ \vdots \\ Y_{n-1ghf} \\ Y_{nghf} \end{bmatrix} = \begin{bmatrix} 1 & A_{1111} & X_{1111} & W_{1111} & Z_{1111} & ... & A_{1111}X_{1111}W_{1111}Z_{1111} \\ 1 & A_{2111} & X_{2111} & W_{2111} & Z_{2111} & ... & A_{2111}X_{2111}W_{2111}Z_{2111} \\ 1 & A_{3111} & X_{3111} & W_{3111} & Z_{3111} & ... & A_{3111}X_{3111}W_{3111}Z_{3111} \\ & & & \vdots & & & \\ 1 & A_{n-1ghf} & X_{n-1ghf} & W_{n-1ghf} & Z_{n-1ghf} & ... & A_{n-1ghf}X_{n-1ghf}W_{n-1ghf}Z_{n-1ghf} \\ 1 & A_{nghf} & X_{nghf} & W_{nghf} & Z_{nghf} & ... & A_{nghf}X_{nghf}W_{nghf}Z_{nghf} \end{bmatrix} \begin{bmatrix} \delta_{0000} \\ \delta_{0001} \\ \delta_{0010} \\ \delta_{0011} \\ \delta_{0100} \\ \delta_{0101} \\ \delta_{0110} \\ \delta_{0111} \\ \delta_{1000} \\ \delta_{1001} \\ \delta_{1010} \\ \delta_{1011} \\ \delta_{1100} \\ \delta_{1101} \\ \delta_{1110} \\ \delta_{1111} \end{bmatrix}
$$

$$
+ \begin{bmatrix} r_{1111}A_{1111} + u_{1011}A_{1111} + +v_{1001}A_{1111} + ... + v_{0001} + r_{0111} + u_{0011} + e_{1111} \\ r_{1111}A_{2111} + u_{1011}A_{2111} + +v_{1001}A_{2111} + ... + v_{0001} + r_{0111} + u_{0011} + e_{2111} \\ r_{1111}A_{3111} + u_{1011}A_{3111} + +v_{1001}A_{3111} + ... + v_{0001} + r_{0111} + u_{0011} + e_{3111} \\ \vdots \\ r_{1ghf}A_{n-1ghf} + u_{10hf}A_{n-1ghf} + +v_{100f}A_{n-1ghf} + ... + v_{000f} + r_{0ghf} + u_{00hf} + e_{n-1ghf} \\ r_{1ghf}A_{n-1ghf} + u_{10hf}A_{nghf} + +v_{100f}A_{nghf} + ... + v_{000f} + r_{0ghf} + u_{00hf} + e_{nghf} \end{bmatrix},
$$

for $\mathbf{Y} = [Y_{1111}, Y_{2111}, ..., Y_{nghf}]'$ and $Y_{ijkl} \sim N(\mathbf{M}\delta, \mathbf{\Sigma})$. Recall, A_{ijkl}, X_{ijkl}, W_{ijkl}, and Z_{ijkl} are independent. Therefore,

$$\Sigma_{ijkl} = Var(Y_{ijkl})$$

$$= Var(\delta_{0000} + \delta_{1000}A_{ijkl} + \delta_{0100}X_{ijkl} + \delta_{0010}W_{ijkl} + \delta_{0001}Z_{ijkl} + \delta_{1100}A_{ijkl}X_{ijkl}$$

$$+ \delta_{1010}A_{ijkl}W_{ijkl}$$

The standard error of each parameter $\hat{\delta}_{\mathbf{ijkl}}$ are the analogous diagonal elements derived in Appendix A. That is, generally $s.e.(\mu) = \sqrt{\mathbf{\Sigma(M'M)^{-1}}}$ (Appendix A). Therefore, for a Level-4 HLM $s.e.(\hat{\delta}) = \sqrt{\sigma^2_{Level-4}\mathbf{I}_{N\times N}\mathbf{D}^{-1}_{Level-4}}$. If the Level-4 HLM predictors have the following distributions $A_{ijkl} \sim N(0, \sigma_A^2)$, $X_{ijkl} \sim N(0, \sigma_X^2)$, $W_{ijkl} \sim N(0, \sigma_W^2)$, and $Z_{ijkl} \sim N(0, \sigma_Z^2)$, then the elements of $\mathbf{D}_{Level-4}$ are:

$$d_{1,1} = \sum_{l=1}^{f}\sum_{k=1}^{h}\sum_{j=1}^{g}\sum_{i=1}^{n} 1 = nghf = N,$$

$$d_{1,2} = d_{2,1} = \sum_{l=1}^{f}\sum_{k=1}^{h}\sum_{j=1}^{g}\sum_{i=1}^{n} A_{ijkl} = nghfE[A_{ijkl}] = N\mu_A = N(0) = 0,$$

$$= N(cov(A_{ijkl}X_{ijkl}^2, W_{ijkl}^2 Z_{ijkl}^2) + E[A_{ijkl}X_{ijkl}^2]E[W_{ijkl}^2 Z_{ijkl}^2])$$

$$= N(0 + (cov(A_{ijkl}, X_{ijkl}^2) + E[A_{ijkl}]E[X_{ijkl}^2])(cov(W_{ijkl}^2, Z_{ijkl}^2) + E[W_{ijkl}^2]E[Z_{ijkl}^2])$$

$$= N(0 + (0 + (\mu_A)(\sigma_X^2 + \mu_X^2))(0 + (\sigma_W^2 + \mu_W^2)(\sigma_Z^2 + \mu_Z^2))$$

$$= N(0 + (0 + (0)(\sigma_X^2 + 0))(0 + (\sigma_W^2 + 0)(\sigma_Z^2 + 0)) = 0,$$

$$d_{16,16} = \sum_{l=1}^{f}\sum_{k=1}^{h}\sum_{j=1}^{g}\sum_{i=1}^{n}(A_{ijkl}X_{ijkl}W_{ijkl}Z_{ijkl})^2 = nghfE[(A_{ijkl}X_{ijkl}W_{ijkl}Z_{ijkl})^2]$$

$$= NE[A_{ijkl}^2 X_{ijkl}^2 W_{ijkl}^2 Z_{ijkl}^2]$$

$$= N(cov(A_{ijkl}^2 X_{ijkl}^2, W_{ijkl}^2 Z_{ijkl}^2) + E[A_{ijkl}^2 X_{ijkl}^2]E[W_{ijkl}^2 Z_{ijkl}^2])$$

$$= N(0 + (cov(A_{ijkl}^2, X_{ijkl}^2) + E[A_{ijkl}^2]E[X_{ijkl}^2])(cov(W_{ijkl}^2, Z_{ijkl}^2) + E[W_{ijkl}^2]E[Z_{ijkl}^2])$$

$$= N(0 + (0 + (\sigma_A^2 + \mu_A^2)(\sigma_X^2 + \mu_X^2))(0 + (\sigma_W^2 + \mu_W^2)(\sigma_Z^2 + \mu_Z^2))$$

$$= N(0 + (0 + (\sigma_A^2 + 0)(\sigma_X^2 + 0))(0 + (\sigma_W^2 + 0)(\sigma_Z^2 + 0))$$

$$= N\sigma_A^2\sigma_X^2\sigma_W^2\sigma_Z^2.$$

Hence by substitution, this implies

$$
\mathbf{D}_{Level-4} = \begin{bmatrix}
N & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & N\sigma_A^2 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & N\sigma_X^2 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & \ddots & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & \ddots & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & N\sigma_A^2\sigma_W^2\sigma_Z^2 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & N\sigma_X^2\sigma_W^2\sigma_Z^2 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & N\sigma_A^2\sigma_X^2\sigma_W^2\sigma_Z^2
\end{bmatrix}.
$$

The inverse of the diagonal matrix $\mathbf{D}_{Level-4}$ is denoted $\mathbf{D}_{Level-4}^{-1}$ and equivalent to

$$
\mathbf{D}_{Level-4}^{-1} = \begin{bmatrix}
\frac{1}{N} & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & \frac{1}{N\sigma_A^2} & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & \frac{1}{N\sigma_X^2} & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & \ddots & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & \ddots & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & \frac{1}{N\sigma_A^2\sigma_W^2\sigma_Z^2} & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & \frac{1}{N\sigma_X^2\sigma_W^2\sigma_Z^2} & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & \frac{1}{N\sigma_A^2\sigma_X^2\sigma_W^2\sigma_Z^2}
\end{bmatrix}.
$$

By Appendix A, $Var(\hat{\delta}) = \sigma^2_{Level-4}\mathbf{I}_{N\times N}\mathbf{D}^{-1}_{Level-4}$. Therefore,

$$Var(\delta) = \begin{bmatrix} \frac{\sigma^2_{Level-4}}{N} & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & \frac{\sigma^2_{Level-4}}{N\sigma^2_A} & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & \frac{\sigma^2_{Level-4}}{N\sigma^2_X} & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & \ddots & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & \ddots & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & \frac{\sigma^2_{Level-4}}{N\sigma^2_A\sigma^2_W\sigma^2_Z} & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & \frac{\sigma^2_{Level-4}}{N\sigma^2_X\sigma^2_W\sigma^2_Z} & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & \frac{\sigma^2_{Level-4}}{N\sigma^2_A\sigma^2_X\sigma^2_W\sigma^2_Z} \end{bmatrix}.$$

Hence, $s.e.(\hat{\delta}) = \sqrt{\sigma^2_{Level-4}I_{NxN}\mathbf{D}^{-1}_{Level-4}}$. Thus,

$$s.e.(\delta) = \begin{bmatrix} \sqrt{\frac{\sigma^2_{Level-4}}{N}} & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & \sqrt{\frac{\sigma^2_{Level-4}}{N\sigma^2_A}} & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & \sqrt{\frac{\sigma^2_{Level-4}}{N\sigma^2_X}} & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & \ddots & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & \ddots & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & \sqrt{\frac{\sigma^2_{Level-4}}{N\sigma^2_A\sigma^2_W\sigma^2_Z}} & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & \sqrt{\frac{\sigma^2_{Level-4}}{N\sigma^2_X\sigma^2_W\sigma^2_Z}} & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & \sqrt{\frac{\sigma^2_{Level-4}}{N\sigma^2_A\sigma^2_X\sigma^2_W\sigma^2_Z}} \end{bmatrix}. \tag{30}$$

The derived HLM standard error matrices by Level-2, Level-3, and Level-4 will be used to determine power of the parameters in the Sample Size Estimation for Level-2, Level-3, and Level-4 Section (Section 3.1). For a single independent predictor at each level (A_{ijkl}, X_{ijkl}, W_{ijkl}, and Z_{ijkl}) with corresponding distribution $N(0, \sigma^2_A)$, $N(0, \sigma^2_X)$, $N(0, \sigma^2_W)$, and $N(0, \sigma^2_Z)$ respectively, the standard error matrices will estimate an explicit power expression for various: sample sizes at each level, initial error variance values, error

distributions, predictor distributions, and estimated effect sizes.

3.1 Sample Size Estimation for Level-2, Level-3, and Level-4

To determine the sample size requirements for a Level-2, Level-3, and Level-4 HLM based on adequate power of 0.80 for parameter estimation, a simulation procedure of various scenarios was conducted. Using the combined Level-2, Level-3 and Level-4 HLM equations found in the previous chapter for all levels considered, samples sizes were rounded up to the next highest integer to assume sufficient power. Further, the use of the word "simulation" here refers to the fixed settings for which power was computed. The formulas derived are exact and can be applied to any multi-level model.

Level-2 HLM Sample Size Recommendations.

To accomplish Research Objective 1 for the Level-2 HLM, this research used the combined Level-2 HLM measurement model specified in Equation 22 and restated here: $Y_{ij} = \beta_{00} + \beta_{01}X_{ij} + \beta_{10}A_{ij} + \beta_{11}X_{ij}A_{ij} + r_{1j}A_{ij} + r_{0j} + e_{ij}$. Five conditions were considered to determine the sample size requirements to achieve sufficient power for parameter estimation of a Level-2 HLM. The five conditions and the number of levels used in the simulation were:

1) the number of individuals and groups at Level-1 and Level-2, respectively, varied between 1 and 100;

2) two initial Level-1 error variances ($\sigma_e^2 = 1.0, 2.0$);

3) two cases for Level-2 error variance in which either Level-2 equals Level-1 error variance or Level-2 error variance is twice that of Level-1 (Table 2);

4) three simulation cases for predictor distribution by level (Table 3); and

5) three levels of parameter estimated effect sizes (0.1, 0.3, 0.7).

The error variance assumptions by level were based on realistic operational distributions where the variability of individuals at Level-1 is greater than or equal to the variability of groups at Level-2. These values are shown in Table 2. Unlike previous studies, the error variance levels were chosen instead of ICC values as in previous practice. This is because information about error variance rather than ICC most likely would be known. This research used $e_{ijkl} \sim N(0, \sigma_e^2)$, such that $\sigma_e^2 = 1.0$ at Level-1 as a comparison to previous Level-2 HLM power analysis studies. The error variance assumptions and variance terms were chosen similar to literature such that the corresponding ICC values were moderate as shown in Table 4.

Table 2. Level-2: initial Level-1 error variance and associated error variance values for each simulation case

Initial Level-1 Value	**Level**	**Error Variance Assumptions** Simulation Case		**Error Variance Values** Simulation Case	
		1	2	1	2
$\sigma_e^2 = 1.0$	1	$2\sigma_e^2$	σ_e^2	2.0	1.0
	2	σ_e^2	σ_e^2	1.0	1.0
$\sigma_e^2 = 2.0$	1	$2\sigma_e^2$	σ_e^2	4.0	2.0
	2	σ_e^2	σ_e^2	2.0	2.0

Table 3. Level-2: Distribution assumptions for predictor assumptions by level

Level	**Predictor Distribution**	**Predictor Variance Term**	**Variance Values for Simulation Case** 1	2	3
1	$A_{ij} \sim N(0, \sigma_A^2)$	σ_A^2	1.0	0.5	1.0
2	$X_{ij} \sim N(0, \sigma_X^2)$	σ_X^2	1.0	1.0	0.5

Level-2 HLM Power Simulation Results.

The power, first generally introduced in Equation 19, of a Level-2 HLM is

$$z_\pi \approx \Phi\left(\frac{\hat{\beta} - \beta}{s.e.(\hat{\beta})} - z_{1-\alpha/2}\right)$$

Table 4. Level-2: intraclass correlation (ICC) values for the proportion of variance within group-level

Simulation Case	Variance Values by Level Level-1 Level-2	Intraclass Correlation $ICC_1 = \frac{\sigma_r^2}{\sigma_e^2+\sigma_r^2}$
1	$\sigma_e^2 = 2.0$ $\sigma_r^2 = 1.0$ $\sigma_e^2 = 4.0$ $\sigma_r^2 = 2.0$	$ICC_1 = \frac{1}{2+1} = 0.333$ $ICC_1 = \frac{2}{4+2} = 0.333$
2	$\sigma_e^2 = 1.0$ $\sigma_r^2 = 1.0$ $\sigma_e^2 = 2.0$ $\sigma_r^2 = 2.0$	$ICC_1 = \frac{1}{1+1} = 0.5$ $ICC_1 = \frac{2}{2+2} = 0.5$

such that:

π is the minimum power considered equal to 0.80;

z_π is $z_{0.80}$ for the minimum power considered. Based on the standard normal table, the z-score is 0.7881;

$\hat{\beta} - \beta$ is the estimated effect size for the assumed values $0.1, 0.3,$ and 0.7;

$z_{1-\alpha/2}$ is $z_{0.975}$ assuming the Type I error rate, α is equal to 0.05. Based on the standard normal table, the z-score is 1.96;

$s.e.(\hat{\beta})$ are the derived diagonal elements of the $s.e.(\hat{\beta})$ matrix for the parameter vector $[\beta_{00}, \beta_{01}, \beta_{10}, \beta_{11}]$ as given in Equation 19.

For equal and varying sample sizes at Level-1 and Level-2, the power is computed for each sample set of the five conditions outlined in the Level-2 HLM simulation procedure (Table 5 and Figures 11 to 15). Based on the assumed predictor variances, the figures illustrate plot comparisons for Level-2 intercepts (β_{00}, β_{10}) and slopes (β_{01}, β_{11}) when $\sigma_A^2 = \sigma_X^2 = 1$ (Figure 11), the intercept and slope of the Level-1 intercept parameter equations when $\sigma_A^2 = 0.5$ and $\sigma_X^2 = 1$ (Figure 12), the intercept and slope (β_{10}, β_{11}) of the Level-1 slope parameter equations when $\sigma_A^2 = 0.5$ and $\sigma_X^2 = 1$ (Figure 13), pure intercepts (β_{00}, β_{10}) when $\sigma_A^2 = 1.0$ and $\sigma_X^2 = 0.5$ (Figure 14), and slopes of large interactions (β_{01}, β_{11}) when $\sigma_A^2 = 0.5$ and $\sigma_X^2 = 1.0$ (Figure 15).

The specific sample size recommendations to achieve at least 0.80 power for $n = g$ and the smallest sample size pair (n, g) for each predictor and error distribution are outlined in Table 5. The smallest sample size pair refers to the pair in which the smallest value for Level-1 or Level-2 is found that still results in at least 80% power. That is, numbers within the (n, g) set are interchangeable between levels and are conventionally listed smallest to

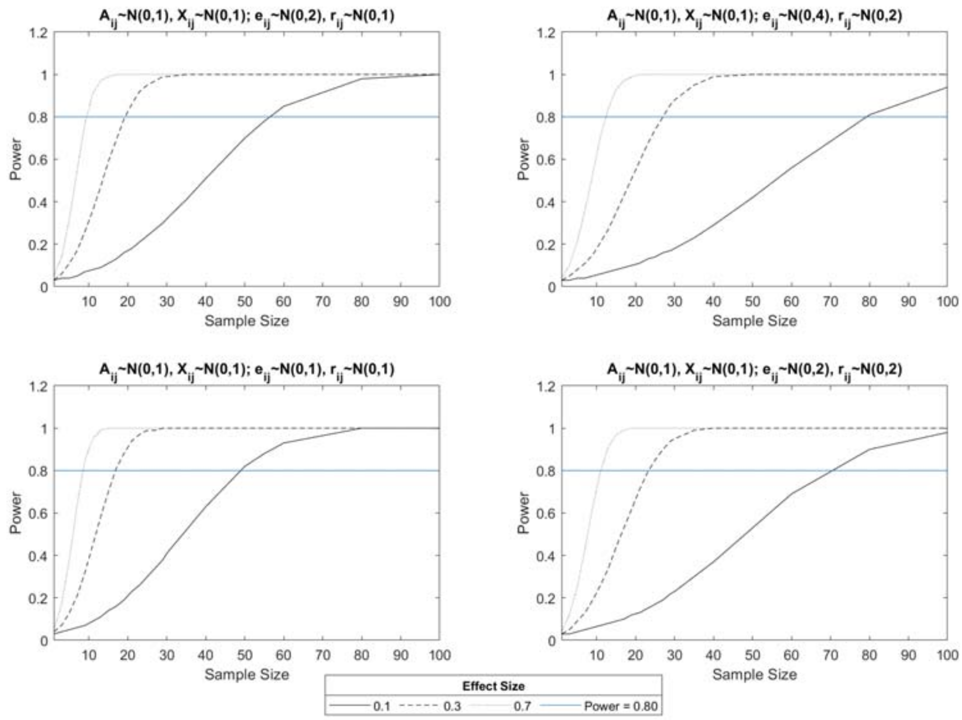

Figure 11. Level-2 HLM power versus sample size plots for intercepts (β_{00} and β_{10}) and slopes (β_{01} and β_{11}) with predictor variances $\sigma_A^2 = \sigma_X^2 = 1.0$.

largest. For comparison, this research associates the first number, n, with Level-1 and the second number, g, with Level-2.

Previous Level-2 HLM analysis, detailed in Chapter 2, primarily looked at the cases with predictor variance $\sigma_A^2 = 1.0$ and $\sigma_X^2 = 1.0$ and Level-1 error variance 1.0 at Level-1 for varying ICC values (which then determined the error variance term for Level-2, σ_r^2). To achieve sufficient power of 0.80 for different estimated effect sizes, this research found that when the Level-1 error variance $\sigma_e^2 = 1.0$, the 30 samples at Level-1 and Level-2 general rule of thumb was not met for low estimated effect sizes (e.g., 0.1), which required 49 samples at each level (Table 5). But for higher estimated effect sizes (0.3 and 0.7), the minimum number of sample sizes at each level was found to be 17 and 9, respectively. That is, about half and less than half of the general rule, respectively (Table 5, Figures 11 and 15). When estimated effect size was moderate (0.3) or large (0.7), adequate power was achievable. For low estimated effect size (0.1), adequate power was also achieved at a

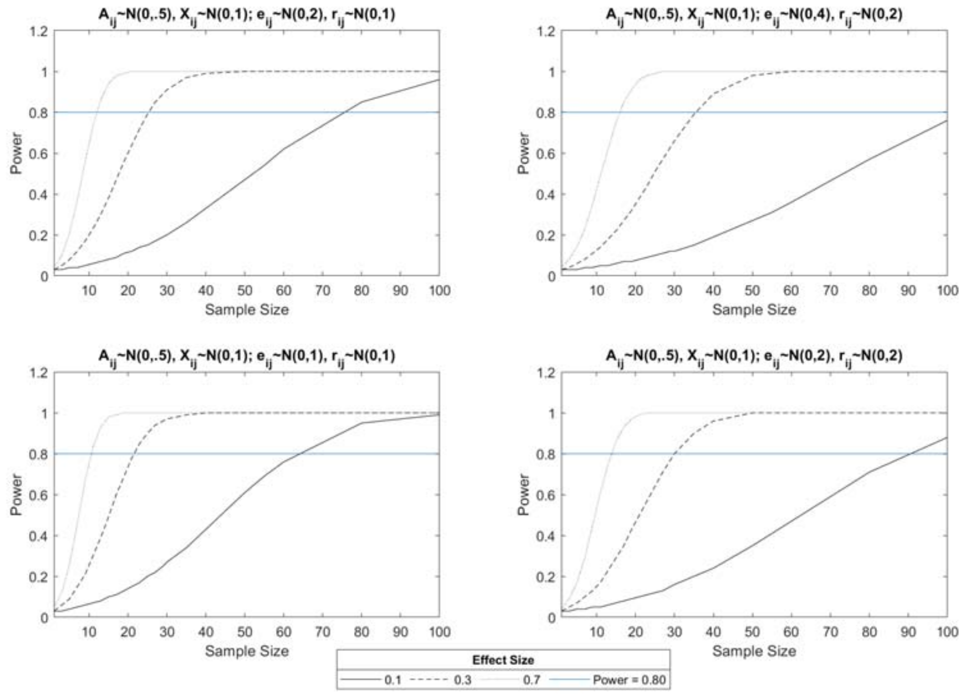

Figure 12. Level-2 HLM power versus sample size plots for Level-1 intercept equations (β_{00} and β_{01}) with predictor variances $\sigma_A^2 = 0.5$ and $\sigma_X^2 = 1.0$.

higher sample size $n = g = 49$.

For all Level-2 predictor variance assumptions when sufficient power of 0.80 was met, as the estimated effect sizes (0.1, 0.3, 07) increased the number of samples required to achieve at least 0.80 power per level decreased. For example, in Table 5, the Level-2 HLM intercepts and slopes with predictor variance $\sigma_A^2 = 1.0$ and $\sigma_X^2 = 1.0$, and error variance $\sigma_e^2 = 2.0$ and $\sigma_r^2 = 1.0$ requires 50, 20, and 10 sample sizes at Level-1 and Level-2 when $n = g$ for estimated effect sizes 0.1, 0.3, and 0.7, respectively. In other words, estimated effect size 0.7 requires 40 fewer sample sizes per level than estimated effect size 0.1. Also, if the smallest pair of (n, g) is considered for the same scenarios, such that the smallest value for Level-1 or Level-2 is considered, 40, 15, and 10 (for n) and 80, 25, and 90 (for g) samples per level for estimated effect sizes 0.1, 0.3, and 0.7, respectively. With unequal sample sizes, estimated effect size 0.7 requires 36.7% fewer overall sample sizes per level than estimated effect size 0.1. The specific Level-2 HLM sample size recommendations to achieve at least 0.80 power for all intercepts and slopes are outlined in Table 5 and Figures

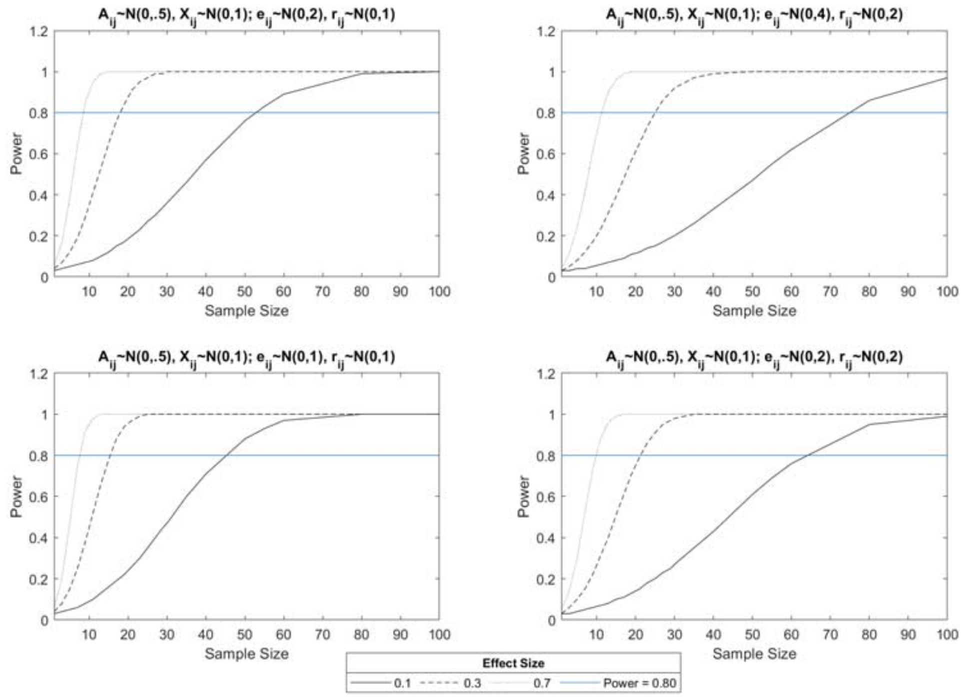

Figure 13. Level-2 HLM power versus sample size plots for Level-1 slope equations (β_{10} and β_{11}) with predictor variances $\sigma_A^2 = 0.5$ and $\sigma_X^2 = 1.0$.

11 to 15.

For all Level-2 HLM parameters ($\beta_{00}, \beta_{10}, \beta_{01}, \beta_{11}$), as the error variance values double (Table 2: Case 1 versus Case 2, and Figures 11 to 15) for all simulation cases, the sample sizes needed per level increased (Table 5). All the Level-2 power versus sample size plots show this when comparing the left-hand side to the right-hand side of each figure (Figures 11 to 15). For example, for the Level-2 HLM slopes (β_{01}, β_{11}) with predictor variance $\sigma_A^2 = 1.0$ and $\sigma_X^2 = 1.0$, when the error variance $\sigma_e^2 = 2.0$ and $\sigma_r^2 = 1.0$ increase to $\sigma_e^2 = 4.0$ and $\sigma_r^2 = 2.0$, the number of samples required at Level-1 and Level-2 when $n = g$ is 23, 7, and 3 more samples per level to achieve at least 0.80 power for estimated effect sizes 0.1, 0.3, and 0.7, respectively (Table 5 and Figure 11). For the same scenario, the smallest pair (n, g) requires an additional 40, 10, and 8 (for n) and 0, 4, 73 (for g) samples per level for estimated effect sizes 0.1, 0.3, and 0.7, respectively (Table 5).

For all scenarios considered, as the error variance at Level-1, σ_e^2, increased, the sample sizes required per level to achieve minimum power of 0.80 for Level-2 HLM parameters

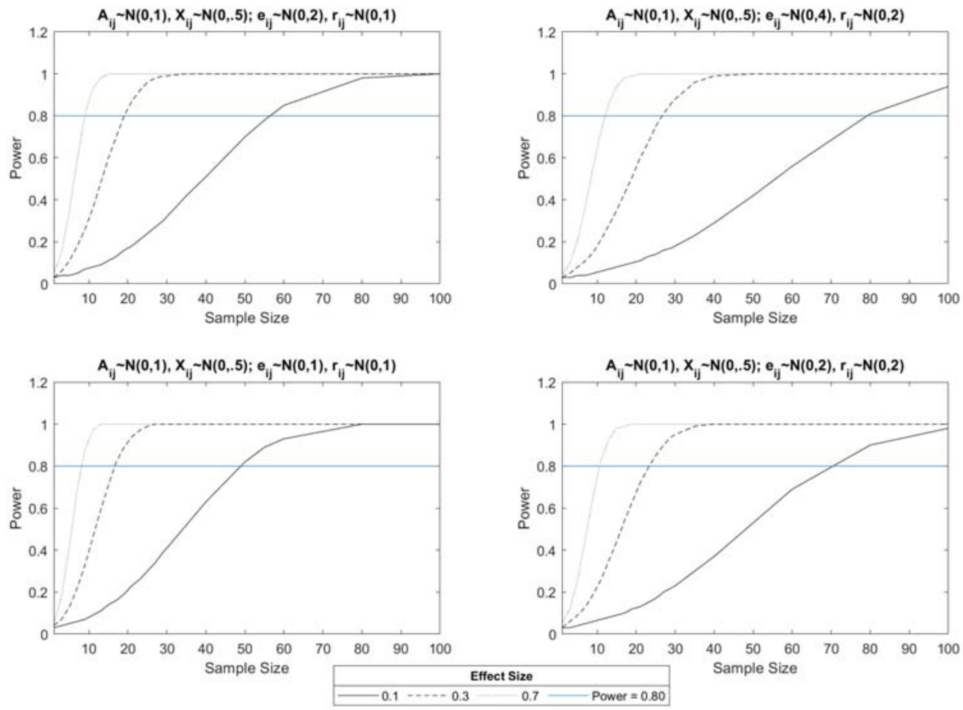

Figure 14. Level-2 HLM power versus sample size plots for pure intercepts (β_{00} and β_{10}) with predictor variances $\sigma_A^2 = 1.0$ and $\sigma_X^2 = 0.5$.

$(\beta_{00}, \beta_{10}, \beta_{01}, \beta_{11})$, increased for all estimated effect sizes. For example, for the Level-2 HLM intercepts and slopes with predictor variance $\sigma_A^2 = \sigma_X^2 = 1.0$ and Level-2 error variance $\sigma_r^2 = 1.0$, when the Level-1 error variance $\sigma_e^2 = 1.0$ increased to $\sigma_e^2 = 2.0$, the number of samples required at Level-1 and Level-2 when $n = g$ is 8, 3, and 1 more samples per level for estimated effect sizes 0.1, 0.3, and 0.7, respectively. The smallest pair (n, g) requires a difference of 10, 2, and 2 (for n) and 0, 8, and 65 (for g) samples per level for estimated effect sizes 0.1, 0.3, and 0.7, respectively (Table 5 and Figure 11: top and bottom).

As the Level-1 predictor variance decreases from $\sigma_A^2 = 1.0$ to 0.5, the sample sizes required per level to achieve a minimum power of 0.80 decreased for intercept and slope (β_{00}, β_{01}) of the Level-1 intercept parameter equations and increased for the intercept and slope (β_{10}, β_{11}) of the Level-1 slope parameter equations for all estimated effect sizes. For example, for the intercept and slope (β_{00}, β_{01}) of the Level-1 intercept parameter equations

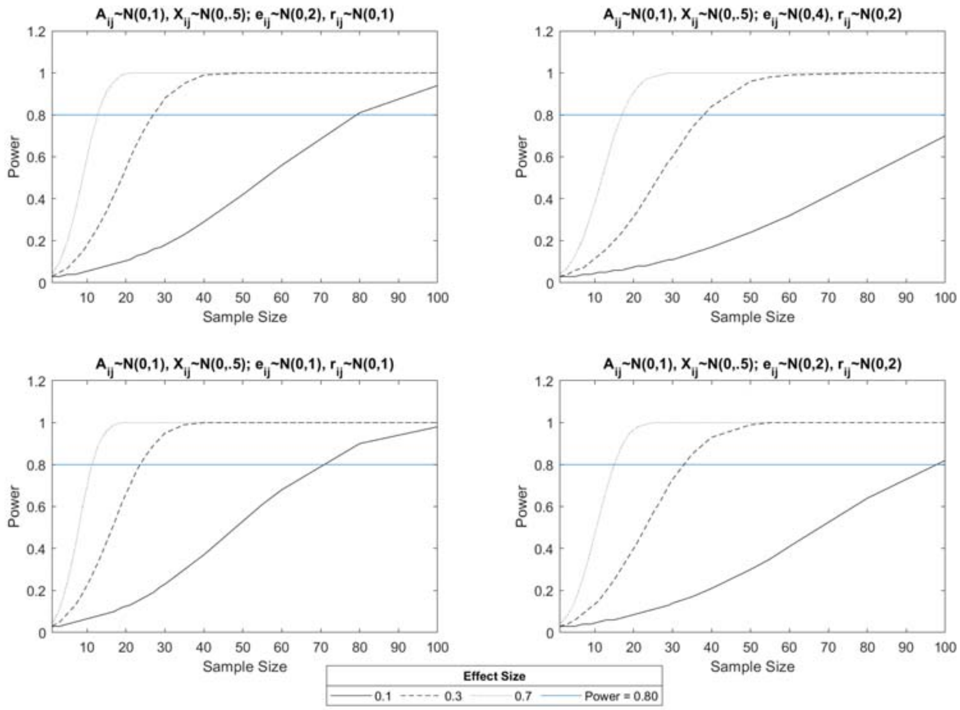

Figure 15. Level-2 HLM power versus sample size plots for large interactions (β_{01} and β_{11}) with predictor variances $\sigma_A^2 = 1.0$ and $\sigma_X^2 = 0.5$.

with predictor variance $\sigma_A^2 = \sigma_X^2 = 1.0$ and error variance $\sigma_e^2 = \sigma_r^2 = 1.0$ compared to Level-1 predictor variance $\sigma_A^2 = 0.5$, the number of samples required at Level-1 and Level-2 for $n = g$ decreased by 5, 1, and 1 fewer sample sizes per level for estimated effect sizes 0.1, 0.3, and 0.7, respectively (Table 5 and Figure 12). Whereas, for the intercept and slope (β_{10}, β_{11}) of the Level-1 HLM slope parameter equations, the number of samples required at Level-1 and Level-2 for $n = g$ increased by 15, 5, and 2 more sample sizes per level for estimated effect sizes 0.1, 0.3, and 0.7, respectively (Table 5 and Figure 13).

As the Level-2 predictor variance decreases from $\sigma_X^2 = 1.0$ to 0.5, the sample sizes required per level are the same for pure intercepts (β_{00}, β_{10}) and increase for large interactions (β_{01}, β_{11}) when sufficient power of 0.80 is achieved. For example, for the Level-2 HLM intercepts with predictor variance $\sigma_A^2 = \sigma_X^2 = 1.0$ and error variance $\sigma_e^2 = \sigma_r^2 = 1.0$ compared to pure intercepts with Level-2 predictor distribution $\sigma_X^2 = 0.5$, the number of required sample sizes at Level-1 and Level-2 when $n = g$ require the same

number of sample sizes per level for estimated effect size 0.1 and 0,3, with the exception of sample size rounding for estimated effect size 0.7 (Table 5 and Figure 11 and 14). Whereas, for the same scenario for large interactions, the number of required sample sizes at Level-1 and Level-2 when $n = g$ requires a difference of 23, 8, and 1 sample sizes per level for effects sizes 0.1, 0.3, and 0.7, respectively (Table 5 and Figure 11 and 15).

In general, for a Level-2 HLM to achieve sufficient power of 0.80 for different estimated effect sizes this research found that:

- 30 samples at Level-1 and Level-2 general rule of thumb was not met for low estimated effect sizes (e.g., 0.1), which required at least 49 samples at each level. But for higher estimated effect sizes (0.3 and 0.7), the minimum number of samples at each level was found to be 17, almost half of the general rule.

- As the estimated effect sizes (0.1, 0.3, 07) increased for all parameters $(\beta_{00}, \beta_{10}, \beta_{01}, \beta_{11})$ the number of samples required per a level decreased.

- When error variance (σ_e^2 and σ_r^2) values double (Figures 11 to 15 right-hand side compared to left-hand side) for both intercepts (β_{00}, β_{10}) and slopes (β_{01}, β_{11}), the sample sizes needed per level increased.

- If the error variance at Level-1, σ_e^2, increased, the sample sizes required for all parameters increased for all estimated effect sizes considered.

- As the predictor variance at Level-1, σ_A^2, decreased from 1.0 to 0.5, the sample sizes for decreased for Level-1 intercept parameter equations (β_{00}, β_{01}) and increased for Level-1 slope parameter equations (β_{10}, β_{11}) for all estimated effect sizes.

- When the predictor variance at Level-2, σ_X^2, decreased from 1.0 to 0.5, the sample sizes required per level increases for the large interactions (β_{01}, β_{11}) and sample sizes did not change for pure intercepts (β_{00}, β_{10}).

For this Level-2 HLM simulation all sample sizes tables for every combination is provided in Appendix B.1.

Level-3 HLM Sample Size Recommendations.

Similar to the Level-2 HLM simulation procedure, this research used the combined Level-3 HLM measurement model specified in Equation 44 and restated here: $Y_{ijk} = \gamma_{000} + \gamma_{010}X_{ijk} + \gamma_{001}W_{ijk} + \gamma_{011}X_{ijk}W_{ijk} + \gamma_{100}A_{ijk} + \gamma_{101}A_{ijk}W_{ijk} + \gamma_{110}A_{ijk}X_{ijk} + \gamma_{111}A_{ijk}X_{ijk}W_{ijk} + u_{11k}A_{ijk}X_{ijk} + u_{00k} + u_{01k}X_{ijk} + u_{10k}A_{ijk} + r_{1jk}A_{ijk} + r_{0jk} + e_{ijk}$. To accomplish Research Objective 1 Level-3 HLM analysis, five conditions were considered to determine the sample size requirements for a Level-3 HLM. The five conditions considered were:

1) the number of individuals, groups, and units at Level-1, Level-2 and Level-3, respectively, varied between 1 and 100;

2) two initial Level-1 error variances ($\sigma_e^2 = 1.0, 2.0$);

3) three cases for Level-3 error variance in which 1) Level-3, Level-2, and Level-1 decrease in values 2) Level-3 and Level-2 equal Level-1 error variance, and 3) Level-3 and Level-2 error variance is half that of Level-1 (Table 6);

4) three simulation cases for predictor variance in which 1) Level-3 and Level-2 equal Level-1 error variance, 2) Level-3 and Level-2 error variance is twice that of Level-1, and 3) Level-3 and Level-2 are half that of Level-1 (Table 7); and

5) three levels of parameter estimated effect sizes (0.1, 0.3, 0.7).

The three cases for error variance by level were based on realistic operational distributions where the variability of individuals at Level-1 is greater than or equal to the variability of groups and units at higher levels (Level-2 and Level-3). The associated simulation values are shown in Table 6. The error variance assumptions and variance terms were chosen similar to literature of Level-2 HLM analysis and such that the ICC values were generally moderate and largest at the lowest level. The comparable ICC values for each case are given in Table 8.

Table 6. Level-3: initial Level-1 error variance case assumptions and associated error variance values for each simulation case

Initial Level-1 Value	Level	Error Variance Assumptions Simulation Case 1	2	3	Error Variance Values Simulation Case 1	2	3
$\sigma_e^2 = 1.0$	Level-1	$4\sigma_e^2$	σ_e^2	$2\sigma_e^2$	4.0	1.0	2.0
	Level-2	$2\sigma_e^2$	σ_e^2	σ_e^2	2.0	1.0	1.0
	Level-3	σ_e^2	σ_e^2	σ_e^2	1.0	1.0	1.0
$\sigma_e^2 = 2.0$	Level-1	$4\sigma_e^2$	σ_e^2	$2\sigma_e^2$	8.0	2.0	4.0
	Level-2	$2\sigma_e^2$	σ_e^2	σ_e^2	4.0	2.0	2.0
	Level-3	σ_e^2	σ_e^2	σ_e^2	2.0	2.0	2.0

Table 7. Level-3: simulation cases for predictor distributions by level

Level	Predictor Distribution	Predictor Variance Term	Variance Values for Simulation Case 1	2	3
1	$A_{ijkl} \sim N(0, \sigma_A^2$	σ_A^2	1.0	0.5	1.0
2	$X_{ijk} \sim N(0, \sigma_X^2$	σ_X^2	1.0	1.0	0.5
3	$W_{ijk} \sim N(0, \sigma_W^2$	σ_W^2	1.0	1.0	0.5

Level-3 HLM Power Simulation Results.

The power, z_π, first generally introduced in Equation 19, of a Level-3 HLM is

$$z_\pi \approx \Phi\left(\frac{\hat{\gamma} - \gamma}{s.e.(\hat{\gamma})} - z_{1-\alpha/2}\right)$$

such that:

π is the minimum power considered equal to 0.80;

z_π is $z_{0.80}$ for the minimum power considered. Based on the standard normal table, the z-score is 0.7881;

$\hat{\gamma} - \gamma$ is the estimated effect size for the assumed values $0.1, 0.3,$ and 0.7;

$z_{1-\alpha/2}$ is $z_{0.975}$ for the significance value α equal to 0.05. Based on the standard normal

Table 8. Level-3: intraclass correlation (ICC) values for: the proportion of variance of individuals (ICC_1), the proportion of variance among groups (ICC_2), and the proportion of variance of units (ICC_3).

Simulation Case	**Variance Values by Level** Level-1 Level-2 Level-3	**Intraclass Correlation** $ICC_1 = \frac{\sigma_e^2}{\sigma_e^2+\sigma_r^2+\sigma_u^2}$ $ICC_2 = \frac{\sigma_r^2}{\sigma_e^2+\sigma_r^2+\sigma_u^2}$ $ICC_3 = \frac{\sigma_u^2}{\sigma_e^2+\sigma_r^2+\sigma_u^2}$
1	$\sigma_e^2 = 4.0$ $\sigma_r^2 = 2.0$ $\sigma_u^2 = 1.0$	$ICC_1 = \frac{4}{4+2+1} = 0.571$ $ICC_2 = \frac{2}{4+2+1} = 0.286$ $ICC_3 = \frac{1}{4+2+1} = 0.143$
1	$\sigma_e^2 = 8.0$ $\sigma_r^2 = 4.0$ $\sigma_u^2 = 2.0$	$ICC_1 = \frac{8}{8+4+2} = 0.571$ $ICC_2 = \frac{4}{8+4+2} = 0.286$ $ICC_3 = \frac{2}{8+4+2} = 0.143$
2	$\sigma_e^2 = 1.0$ $\sigma_r^2 = 1.0$ $\sigma_u^2 = 1.0$	$ICC_1 = \frac{1}{1+1+1} = 0.333$ $ICC_2 = \frac{1}{1+1+1} = 0.333$ $ICC_3 = \frac{1}{1+1+1} = 0.333$
2	$\sigma_e^2 = 2.0$ $\sigma_r^2 = 2.0$ $\sigma_u^2 = 2.0$	$ICC_1 = \frac{2}{2+2+2} = 0.333$ $ICC_2 = \frac{2}{2+2+2} = 0.333$ $ICC_3 = \frac{2}{2+2+2} = 0.333$
3	$\sigma_e^2 = 2.0$ $\sigma_r^2 = 1.0$ $\sigma_u^2 = 1.0$	$ICC_1 = \frac{2}{2+1+1} = 0.5$ $ICC_2 = \frac{1}{2+1+1} = 0.25$ $ICC_3 = \frac{1}{2+1+1} = 0.25$
3	$\sigma_e^2 = 4.0$ $\sigma_r^2 = 2.0$ $\sigma_u^2 = 2.0$	$ICC_1 = \frac{4}{4+2+2} = 0.5$ $ICC_2 = \frac{2}{4+2+2} = 0.25$ $ICC_3 = \frac{2}{4+2+2} = 0.25$

table, the z-score is 1.96;

$s.e.(\hat{\gamma})$ are the derived diagonal elements of the $s.e.(\gamma)$ matrix for the parameter vector $[\gamma_{000}, \gamma_{100}, \gamma_{010}, \gamma_{110}, \gamma_{001}, \gamma_{101}, \gamma_{011}$ and $\gamma_{111}]$ as given in Equation 16.

For equal and varying sample sizes at Level-1, Level-2 and Level-3, the power is computed for each sample set of the five conditions outlined in the Level-3 HLM simulation procedure (Table 9 and Figures 16 to 21). Based on the assumed predictor variances, the figures illustrate plot comparisons for Level-3 HLM intercepts (γ_{000}, γ_{100}, γ_{010}, γ_{110}) and slopes (γ_{001}, γ_{101}, γ_{011}, γ_{111}) when $\sigma_A^2 = \sigma_X^2 = \sigma_W^2 = 1.0$ (Figure 16), intercepts (γ_{000}, γ_{010}) and slopes (γ_{001}, γ_{011}) for Level-2 intercept parameter equations

Table 9. Level-3 HLM sample size suggestions for sufficient power ($\geq 80\%$) based on assumed predictor variances, error variances, and estimated effect sizes.

Level-3 Sample Size Suggestions

when $\sigma_A^2 = 0.5$ and $\sigma_X^2 = \sigma_W^2 = 1.0$, (Figure 17), intercepts (γ_{100} γ_{110}) and slopes (γ_{101}, and γ_{111}) for Level-2 slope parameter equations when $\sigma_A^2 = 0.5$ and $\sigma_X^2 = \sigma_W^2 = 1.0$ (Figure 18), pure intercepts (γ_{000}, γ_{100}) when $\sigma_A^2 = 1.0$ and $\sigma_X^2 = \sigma_W^2 = 0.5$ (Figure 19), individual predictors of the combined model (γ_{010} γ_{110}, γ_{001}, γ_{101}) when $\sigma_A^2 = 1.0$ and

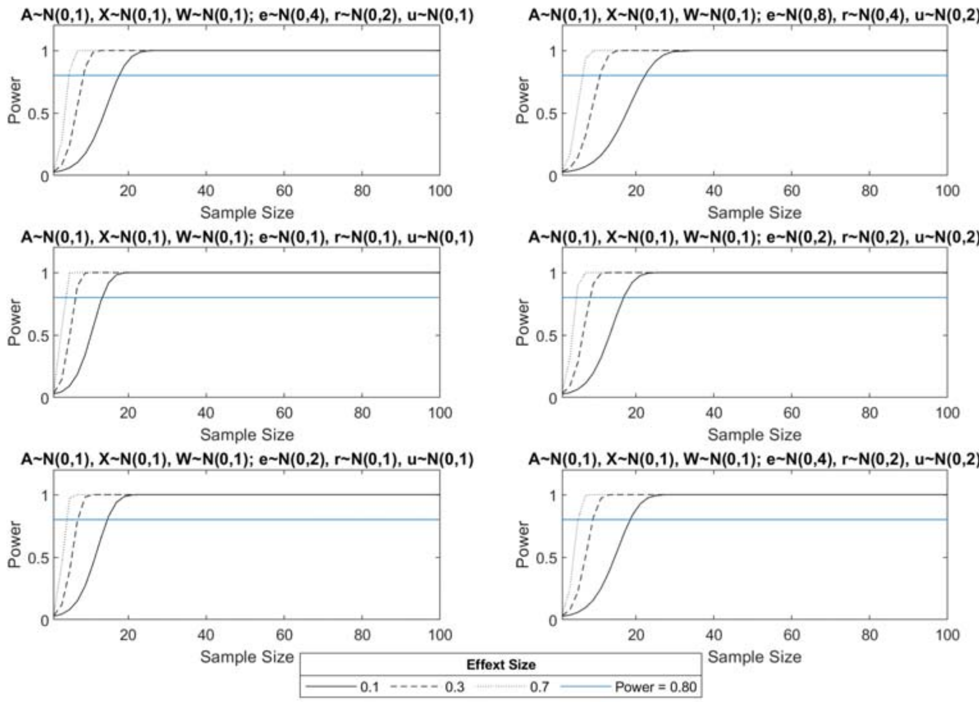

Figure 16. Level-3 HLM power versus sample size plots for intercepts and slopes (γ_{000}, γ_{100}, γ_{010}, γ_{110}, γ_{001}, γ_{101}, γ_{011} and γ_{111}) with $\sigma_A^2 = \sigma_X^2 = \sigma_W^2 = 1.0$.

$\sigma_X^2 = \sigma_W^2 = 0.5$ (Figure 20), and slopes of large interactions (γ_{011}, γ_{111}) when $\sigma_A^2 = 1.0$ and $\sigma_X^2 = \sigma_W^2 = 0.5$ (Figure 21). Notice in each of these figures that overall sufficient power 0.80 is achieved generally with no more than a sample size of 20 per level.

The specific sample size recommendations to achieve at least 0.80 power for $n = g = h$ and the smallest sample size set (n, g, h) for each predictor and error distribution are outlined in Table 9. The smallest sample size set refers to the set in which the smallest value for Level-1, Level-2, or Level-3 is found that results in at least 80% power. That is, numbers within the (n, g, h) set are interchangeable between levels and are conventionally listed smallest to largest. For comparison, this research associates the first number, n, with Level-1, the second number, g, with Level-2, and the third number, h, with Level-3.

Comparing previous Level-2 sufficient sample sizes at each level for a minimum power of 0.80 to Level-3 samples sizes has not been done in previous studies. This research examined the general rule of thumb of 30 samples at each level to the 3rd-level of a Level-3

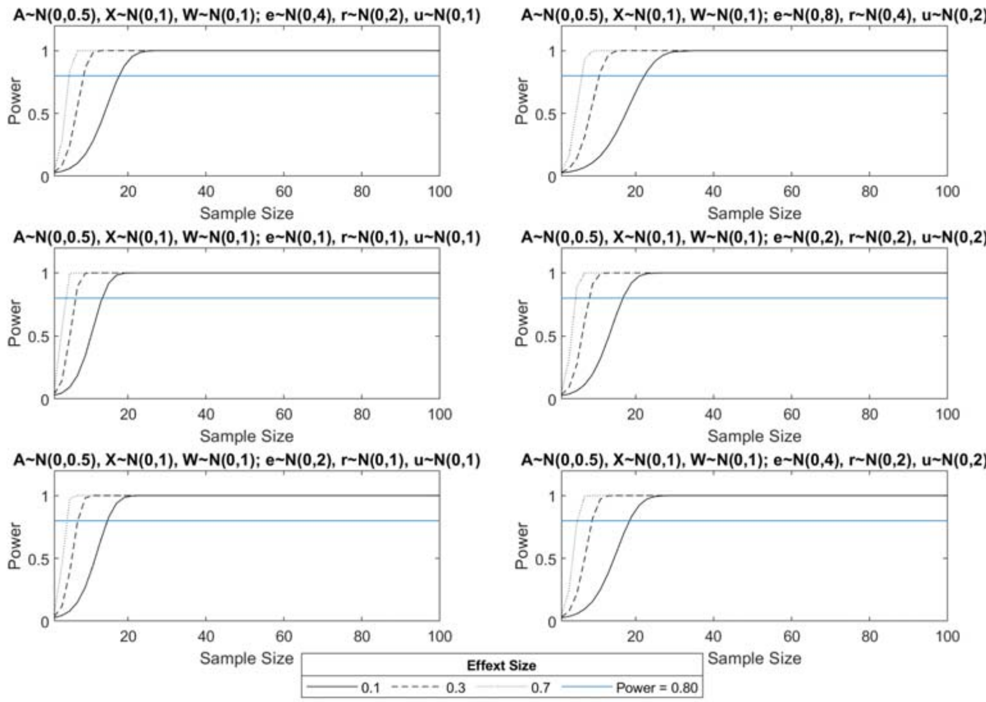

Figure 17. Level-3 HLM power versus sample size plots for intercepts and slopes for Level-1 intercept parameter equations (γ_{000}, γ_{010}, γ_{001}, γ_{011}) with predictor variances $\sigma_A^2 = 0.5$ and $\sigma_X^2 = \sigma_W^2 = 1.0$.

HLM and in Table 9 provided the exact sample size requirements to achieve at least 0.80 power in parameter testing. For different estimated effect sizes this research found that when predictor and error variance at Level-1, Level-2 and Level-3 equals 1.0 ($\sigma_A^2 = \sigma_X^2 = \sigma_W^2 = \sigma_e^2 = \sigma_r^2 = \sigma_u^2 = 1.0$) the assumption of 30 samples at Level-1, Level-2, and Level-3 to achieve a minimum power of 0.80 is more than sufficient because the minimum number of samples needed at each level was found to be 17 for estimated effect size 0.1, almost half of the general rule (Table 9), and 9 an 6 sample sizes per level for estimated effect size 0.3 and 0.7, respectively. In fact, at $n = g = h = 30$ for all estimated effect sizes (0.1, 0.3, 0.7) 1.00 power was achieved as shown in Appendix B.2.

Similar to the Level-2 HLM, for all Level-3 HLM scenarios considered, as the estimated effect size (0.1, 0.3, 0.7) increased, the number of samples for each level required to achieve a minimum power of 0.80 decreased. For example, in Table 9 and Figure 16, the Level-3 HLM intercepts (γ_{000}, γ_{100},γ_{010},γ_{110}) and slopes (γ_{001},γ_{101},γ_{011},γ_{111}) with predictor

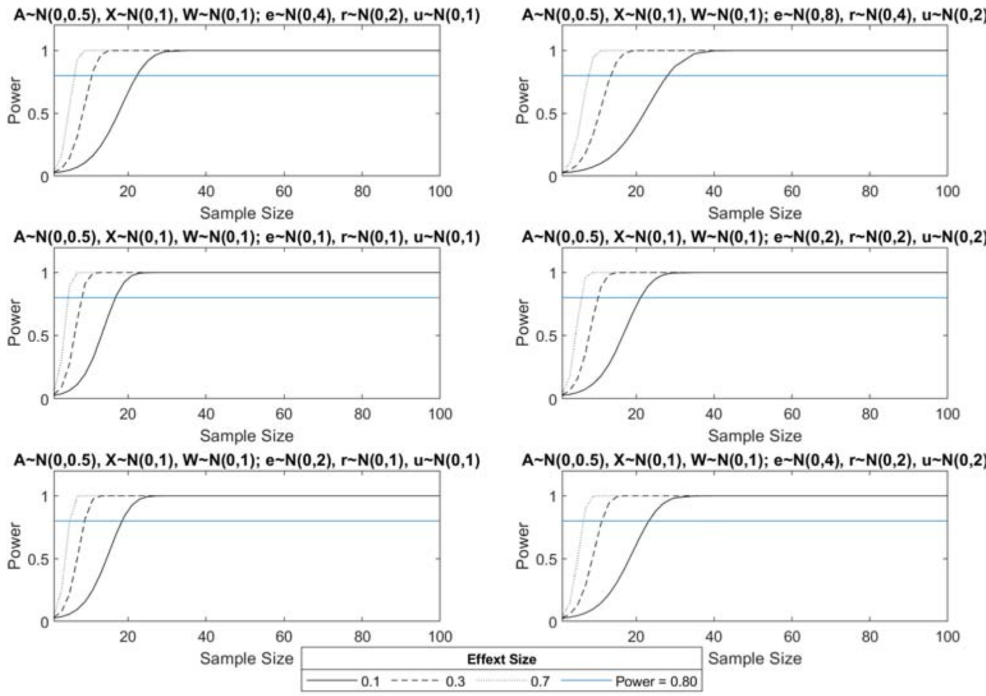

Figure 18. Level-3 HLM power versus sample size plots for intercepts and slopes For Level-1 slope parameter equations (γ_{100}, γ_{110}, γ_{101}, γ_{111}) with predictor variances $\sigma_A^2 = 1.0$ and $\sigma_X^2 = \sigma_W^2 = 0.5$.

variances $\sigma_A^2 = \sigma_X^2 = \sigma_W^2 = 1.0$, and error variances $\sigma_e^2 = 2.0$ and $\sigma_r^2 = \sigma_u^2 = 1.0$ required 18, 9, and 6 samples at Level-1, Level-2, and Level-3 when $n = g = h$ for estimated effect sizes 0.1, 0.3, and 0.7, respectively. In other words, estimated effect size 0.7 required 12 fewer samples per level than estimated effect size 0.1. Also, if the smallest set of (n, g, h) is considered, then the associated sample size sets are (9,23,27), (1,23,29), and (1,13,13) at Level-1, Level-2, and Level-3 for estimated effect sizes 0.1, 0.3, and 0.7, respectively. With unequal sample sizes, estimated effect size 0.7 required 88.9% fewer samples at Level-1, 51.8% fewer samples at Level-2, and 43.5% fewer samples at Level-3 than estimated effect size 0.1 to achieve a minimum power of 0.80. That is the smallest set (n, g, h) required a difference of 8 (for n), 20 (for g), and 24 (for h). Notice, the highest sample size differences are in the higher levels by convention. Furthermore, for larger estimated effect sizes, it is possible to achieve power by sampling a single unit or group.

As the error variance double (Table 6: Case 1 versus Case 2) for all Level-3 HLM

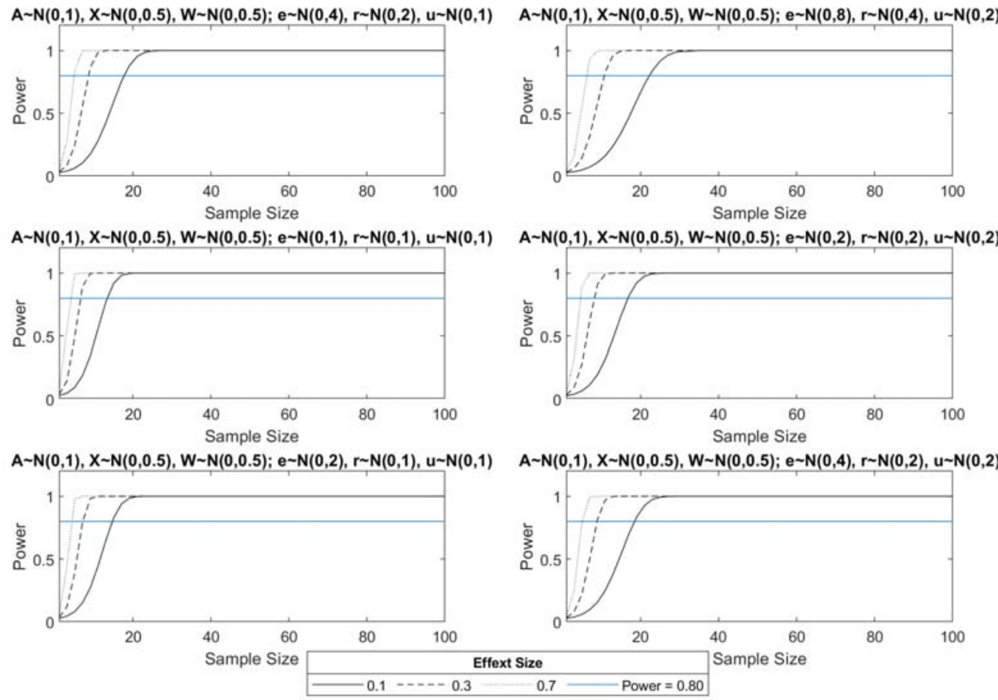

Figure 19. Level-3 HLM power versus sample size plots for pure intercepts (γ_{000},γ_{100}) with predictor variances $\sigma_A^2 = 1.0$ and $\sigma_X^2 = \sigma_W^2 = 0.5$.

predictor and error variance scenarios, the sample sizes needed per level increase to achieve a minimum power of 0.80. This is demonstrated in Figures 16 to 21 when comparing the left-hand side to the right-hand side. For example, for the Level-3 HLM slopes of large interactions ($\gamma_{011}, \gamma_{111}$) with predictor variances $\sigma_A^2 = 1.0$ and $\sigma_X^2 = \sigma_W^2 = 0.5$, when the error variances increases from $\sigma_e^2 = 2.0$ and $\sigma_r^2 = \sigma_u^2 = 1.0$ to $\sigma_e^2 = 4.0$ and $\sigma_r^2 = \sigma_u^2 = 2.0$ the number of required samples at Level-1, Level-2, and Level-3 when $n = g = h$ is 5, 2, and 1 more samples per level for estimated effect sizes 0.1, 0.3, and 0.7, respectively, to achieve a minimum power of 0.80 (Table 6). The smallest set (n, g, h) requires an increase of (8,37,35), (8,4,12), and (0,2,25) samples per each level for estimated effect sizes 0.1, 0.3, and 0.7, respectively (Table 6 and Figure 21).

As the error variance at Level-1, σ_e^2, increases, for all Level-3 HLM predictor variances considered, the sample sizes required to achieve a minimum power of 0.80, increases for all estimated effect sizes (Table 9 and Figures 16 to 21). For example, consider the Level-3

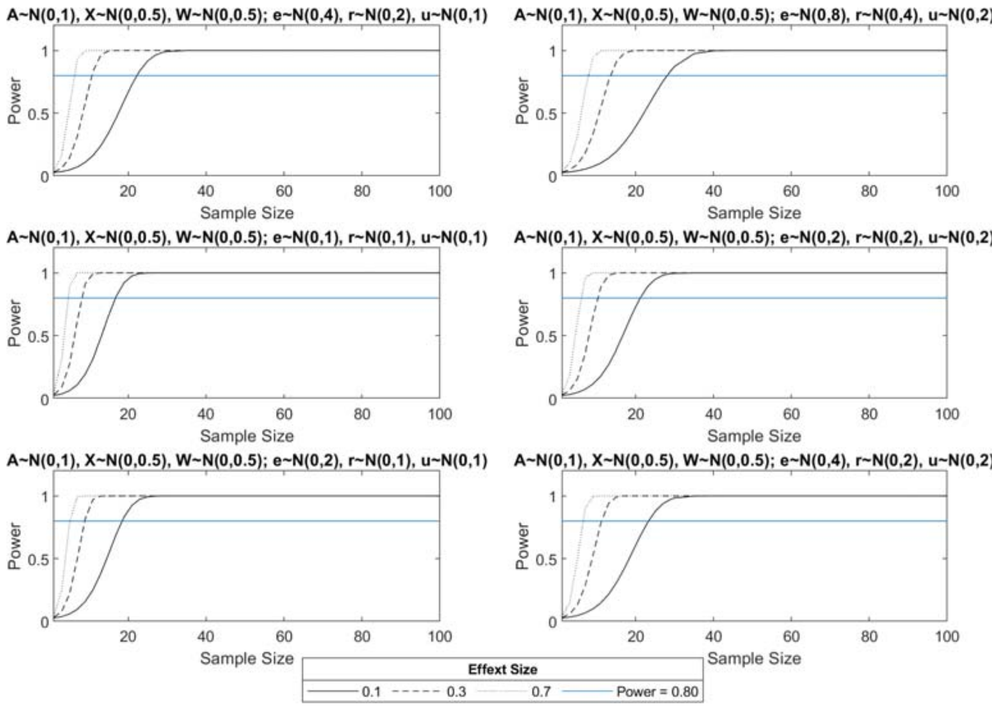

Figure 20. Level-3 HLM power versus sample size plots for intercepts and slopes for individual predictors of the combined Model (γ_{010}, γ_{110}, γ_{001}, γ_{101}) with predictor variances $\sigma_A^2 = 1.0$ and $\sigma_X^2 = \sigma_W^2 = 0.5$.

HLM large interactions $(\gamma_{011}, \gamma_{111})$ with predictor variances $\sigma_A^2 = 1.0$ and $\sigma_X^2 = \sigma_W^2 = 0.5$, and error variances $\sigma_e^2 = \sigma_r^2 = \sigma_u^2 = 1.0$. When the Level-1 error variance doubles from $\sigma_e^2 = 1.0$ to $\sigma_e^2 = 2.0$ the number of required samples at Level-1, Level-2, and Level-3 when $n = g = h$ is 6, 3, and 2 more samples per level for estimated effect sizes 0.1, 0.3, and 0.7, respectively, to achieve a minimum power of 0.80 (Table 9 and Figure 21).

As the predictor variance at Level-1, σ_A^2, decreases from 1.0 to 0.5, the sample sizes required generally stay the same or decrease by 1 sample sizes per a level for all estimated effect sizes for intercepts and slopes $(\gamma_{000}, \gamma_{010}, \gamma_{001,\gamma_{011}})$ of Level-2 intercept parameter equations and increase for intercept and slopes $(\gamma_{100}, \gamma_{110}, \gamma_{101}, \gamma_{111})$ for Level-2 slope parameter equations (Table 9 and Figures 17 to 18). For example, for the Level-3 HLM intercepts and slopes with predictor variances $\sigma_A^2 = \sigma_X^2 = \sigma_W^2 = 1.0$, and error variances $\sigma_e^2 = \sigma_r^2 = \sigma_u^2 = 1.0$ compared to Level-1 predictor variance $\sigma_A^2 = 0.5$ for the intercepts and slopes of the Level-2 slope parameter equations, the number of required samples at

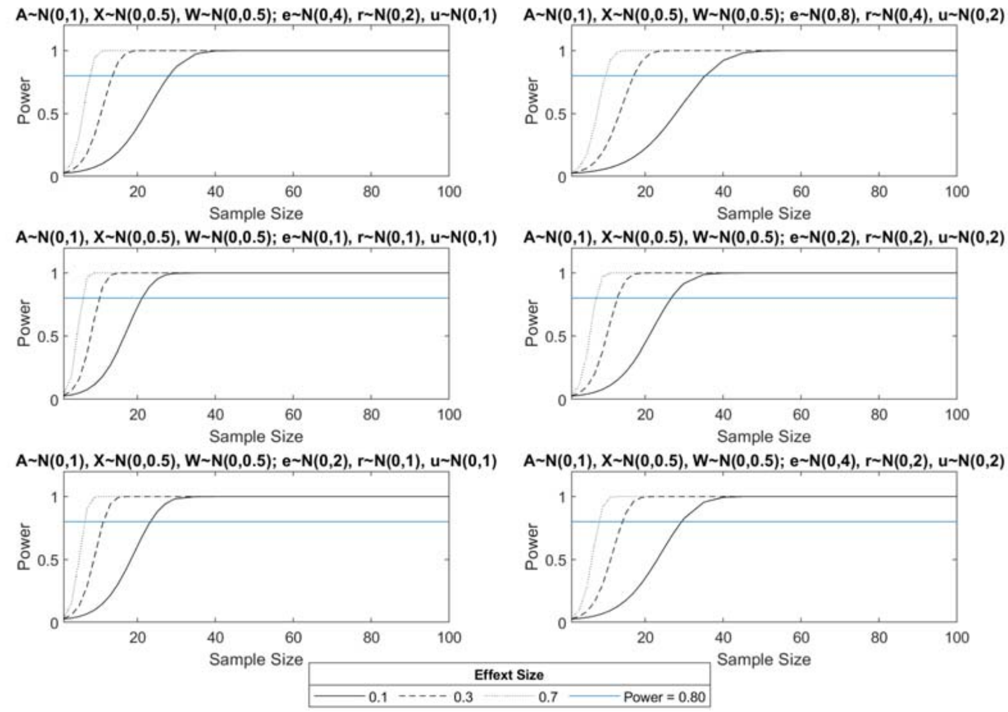

Figure 21. Level-3 HLM power versus sample size plots for slopes of big interactions (γ_{011}, γ_{111}) with predictor variances $\sigma_A^2 = 1.0$ and $\sigma_X^2 = \sigma_W^2 = 0.5$.

Level-1, Level-2, and Level-3 for equal sample sizes ($n = g = h$) is 3, 1, and 1 more samples per level for estimated effect sizes 0.1, 0.3, and 0.7, respectively (Table 9 and Figures 16 to 17). Whereas, to achieve a minimum power of 0.80 when predictor variances $\sigma_A^2 = \sigma_X^2 = \sigma_W^2 = 1.0$, and error variances $\sigma_e^2 = \sigma_r^2 = \sigma_u^2 = 1.0$ compared to Level-1 predictor variance $\sigma_A^2 = 0.5$ for Level-2 intercept parameter equations, the number of required samples at Level-1, Level-2, and Level-3 for equal sample sizes ($n = g = h$) is 1, 1, and 1 fewer sample sizes per level for estimated effect size 0.1, 0.3, and 0.7, respectively (Table 9 and Figure 17).

As the predictor variances at Level-2 and Level-3, σ_X^2 and σ_W^2, decreases from 1.0 to 0.5, the sample sizes required per level to achieve a minimum power of 0.80 generally increases for all estimated effect sizes for pure intercepts ($\gamma_{000}, \gamma_{100}$), individual predictors of the combined model ($\gamma_{010}, \gamma_{110}, \gamma_{001}, \gamma_{101}$), and large interactions ($\gamma_{011}, \gamma_{111}$) (Table 9 and Figures 19 to 21). For example, for the Level-3 HLM predictor distributions

$\sigma_A^2 = \sigma_X^2 = \sigma_W^2 = 1.0$ and error variance $\sigma_e^2 = \sigma_r^2 = \sigma_u^2 = 1.0$ compared to Level-3 predictor variances $\sigma_X^2 = \sigma_W^2 = 0.5$, the number of required samples at Level-1, Level-2, and Level-3 when $n = g = h$ for large interactions $(\gamma_{011}, \gamma_{111})$ is 9, 4, and 2 more samples per level for effects sizes 0.1, 0.3, and 0.7, respectively (Table 9 and Figures 16 and 19). To achieve a minimum power of 0.80, the smallest set (n, g, h) required a difference of (20,6,25), (10,0,32), and (0,6,12) samples per level for estimated effect sizes 0.1, 0.3, and 0.7, respectively (Table 9 and Figures 16 and 19).

In general, Level-3 HLM sample size recommendations and trends are similar to Level-2 conclusions. For a Level-3 HLM to achieve sufficient power of 0.80 for different estimated effect sizes this research found that:

- The general rule of thumb was an over estimate for Level-3 HLM sample size requirements. 30 sample sizes at Level-1 and Level-2 did not extend to Level-3. Low estimated effect sizes (e.g., 0.1) required 17 samples at each level and higher estimated effect sizes (0.3 and 0.7), required a minimum of 9 and 6 sample sizes at each level, respectively.
- As the estimated effect sizes (0.1, 0.3, 07) increase for all Level-3 parameters $(\gamma_{000}, \gamma_{010}, \gamma_{001}, \gamma_{011}, \gamma_{100}, \gamma_{110}, \gamma_{101}, \gamma_{111})$ the number of samples required per level decreased.
- When error variance $(\sigma_e^2, \sigma_r^2, \sigma_u^2)$ values double (Figures 16 to 21 right-hand side compared to left-hand side) for all Level-3 parameters and estimated effect sizes the sample sizes needed per level increased.
- If the error variance at Level-1, σ_e^2, increased, the sample sizes required increased for all estimated effect sizes.
- As the predictor variance at Level-1, σ_A^2, decreased from 1.0 to 0.5, the sample sizes required generally stayed the same or decreased by 1 sample size per level for all estimated effect sizes considered (0.1, 0.3,0.7) for the intercepts and slopes of the

Level-2 intercept parameter equations and increased for Level-2 slope parameter equations.

- When the predictor variances at Level-2 and Level-3, σ_X^2 and σ_W^2, decreased from 1.0 to 0.5, the sample sizes required per level generally increased for individual predictors of the combined model ($\gamma_{010}, \gamma_{110}, \gamma_{001}, \gamma_{101}$) and large interactions ($\gamma_{011}, \gamma_{111}$), while minimally increasing for pure intercepts ($\gamma_{000}, \gamma_{100}$).

For this Level-3 HLM simulation, all sample size tables for every combinations within the simulation are provided in Appendix B.3.

Level-4 HLM Sample Size Recommendations.

Similar to the Level-2 and Level-3 HLM simulation procedure, this research used the combined Level-4 measurement model specified in Equation 29 and restated here: $Y_{ijkl} = \delta_{0000} + \delta_{1000}A_{ijkl} + \delta_{0100}X_{ijkl} + \delta_{0010}W_{ijkl} + \delta_{0001}Z_{ijkl} + \delta_{1100}A_{ijkl}X_{ijkl} + \delta_{1010}A_{ijkl}W_{ijkl} + \delta_{1001}A_{ijkl}Z_{ijkl} + \delta_{0110}X_{ijkl}W_{ijkl} + \delta_{0101}X_{ijkl}Z_{ijkl} + \delta_{0011}W_{ijkl}Z_{ijkl} + \delta_{1110}A_{ijkl}X_{ijkl}W_{ijkl} + \delta_{1101}A_{ijkl}X_{ijkl}Z_{ijkl} + \delta_{1011}A_{ijkl}W_{ijkl}Z_{ijkl} + \delta_{0111}X_{ijkl}W_{ijkl}Z_{ijkl} + \delta_{1111}A_{ijkl}X_{ijkl}W_{ijkl}Z_{ijkl} + v_{111l}A_{ijkl}X_{ijkl}W_{ijkl} + v_{011l}X_{ijkl}W_{ijkl} + v_{101l}A_{ijkl}W_{ijkl} + v_{110l}A_{ijkl}X_{ijkl} + v_{001l}W_{ijkl} + v_{010l}X_{ijkl} + v_{100l}A_{ijkl} + v_{000l} + u_{11kl}A_{ijkl}X_{ijkl} + u_{00kl} + u_{01kl}X_{ijkl} + u_{10kl}A_{ijkl} + r_{1jkl}A_{ijkl} + r_{0jkl} + e_{ijkl}$. To accomplish Research Objective 1 Level-4 HLM analysis, five conditions were considered to determine the sample size requirements for a Level-4 HLM. The five conditions considered were:

1) the number of individuals, groups, units, and organizations at Level-1, Level-2, Level-3, and Level-4, respectively, varied between 1 and 100;

2) two initial Level-1 error variances ($\sigma_e^2 = 1.0, 2.0$);

3) three cases for Level-3 error variance in which 1) Level4, Level-3, Level-2, and Level-1 decrease in values 2) Level-4, Level-3 and Level-2 equal Level-1 error variance, and 3) Level-4, Level-3, and Level-2 error variance is half that of Level-1 (Table 10);

4) three simulation cases for predictor variance in which 1) Level-4, Level-3 and Level-2 equal Level-1 error variance, 2) Level-4, Level-3, and Level-2 error variance is twice that of Level-1, and 3) Level-4, Level-3, and Level-2 are half that of Level-1 (Table 11); and

5) three levels of parameter estimated effect sizes (0.1, 0.3, 0.7).

The three cases for error variance by level were based on realistic operational distributions where the variability of individuals at Level-1 is greater than or equal to the variability of groups, units, and organizations at higher levels (Level-2, Level-3, and Level-4). The associated simulation values are shown in Table 10. The error variance assumptions and variance terms were chosen similar to literature of Level-2 HLM analysis and such that the ICC values were generally moderate and largest at the lowest level. The comparable ICC values for each case is given in Table 12.

Table 10. Level-4: initial Level-1 error variance case assumptions and associated error variance values for each simulation case

Initial Level-1 Value	**Level**	**Error Variance Assumptions** Simulation Case			**Error Variance Values** Simulation Case		
		1	2	3	1	2	3
$\sigma_e^2 = 1.0$	Level-1	$8\sigma_e^2$	σ_e^2	$2\sigma_e^2$	8.0	1.0	2.0
	Level-2	$4\sigma_e^2$	σ_e^2	σ_e^2	4.0	1.0	1.0
	Level-3	$2\sigma_e^2$	σ_e^2	σ_e^2	2.0	1.0	1.0
	Level-4	σ_e^2	σ_e^2	σ_e^2	1.0	1.0	1.0
$\sigma_e^2 = 2.0$	Level-1	$8\sigma_e^2$	σ_e^2	$2\sigma_e^2$	14.0	2.0	4.0
	Level-2	$4\sigma_e^2$	σ_e^2	σ_e^2	8.0	2.0	2.0
	Level-3	$2\sigma_e^2$	σ_e^2	σ_e^2	4.0	2.0	2.0
	Level-4	σ_e^2	σ_e^2	σ_e^2	2.0	2.0	2.0

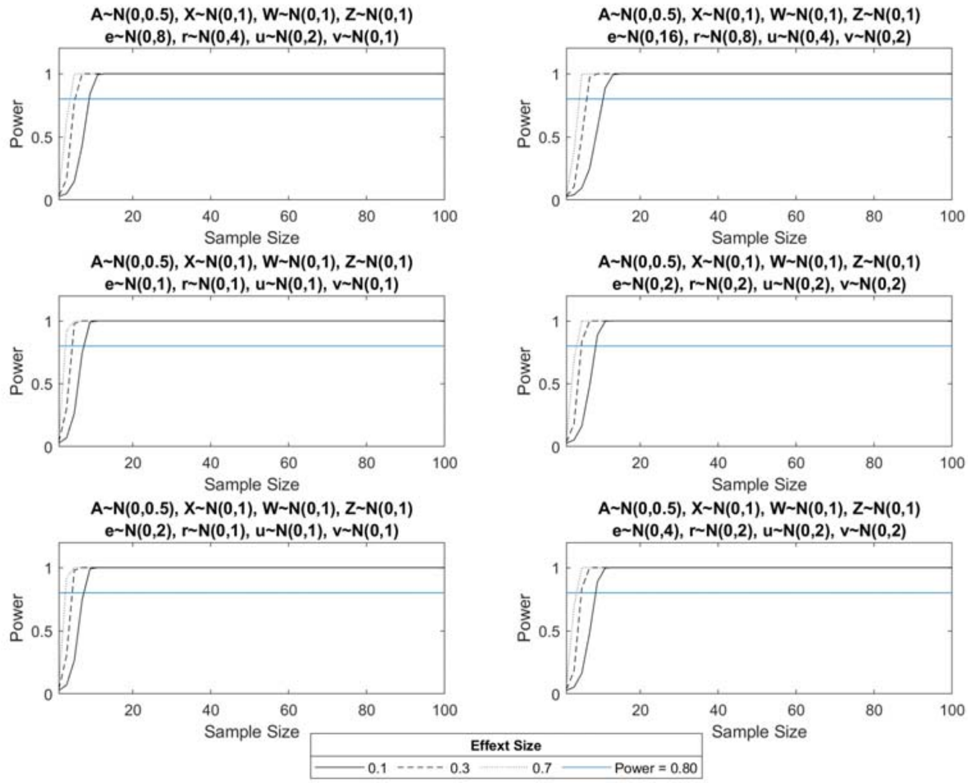

Figure 23. Level-4 HLM power versus sample size plots for intercepts and slopes for Level-3 intercept parameter equations ($\delta_{0000}, \delta_{0100}, \delta_{1000}, \delta_{1100}, \delta_{0001}, \delta_{0101}, \delta_{1001}, \delta_{1101}$) with predictor variances $\sigma_A^2 = 0.5$ and $\sigma_X^2 = \sigma_W^2 = \sigma_Z^2 = 1.0$.

$\hat{\delta} - \delta$ is the estimated effect size for the assumed values $0.1, 0.3,$ and 0.7;

$z_{1-\alpha/2}$ is $z_{0.975}$ for the significance value α equal to 0.05. Based on the standard normal table, the z-score is 1.96;

$s.e.(\hat{\delta})$ are the derived diagonal elements of the $s.e.(\gamma)$ matrix for the parameter vector $[\delta_{0000},\delta_{0100},\delta_{1000},\delta_{1100},\delta_{0010},\delta_{0110},\delta_{1010},\delta_{1110},\delta_{0001},\delta_{0101},\delta_{1001},\delta_{1101},\delta_{0011},\delta_{0111},\delta_{1011},\delta_{1111}]$ as given in Equation 19.

For equal and varying sample sizes at Level-1, Level-2, Level-3 and Level-4, the power is computed for each sample set of the five conditions outlined in the Level-4 HLM simulation procedure (Table 11 and Figures 22 to 28). Based on the assumed predictor variance, the figures illustrate plot comparisons for Level-4 HLM intercepts ($\delta_{0000}, \delta_{0100}, \delta_{1000}, \delta_{1100}, \delta_{0010}, \delta_{0110}, \delta_{1010}, \delta_{1110}$) and slopes

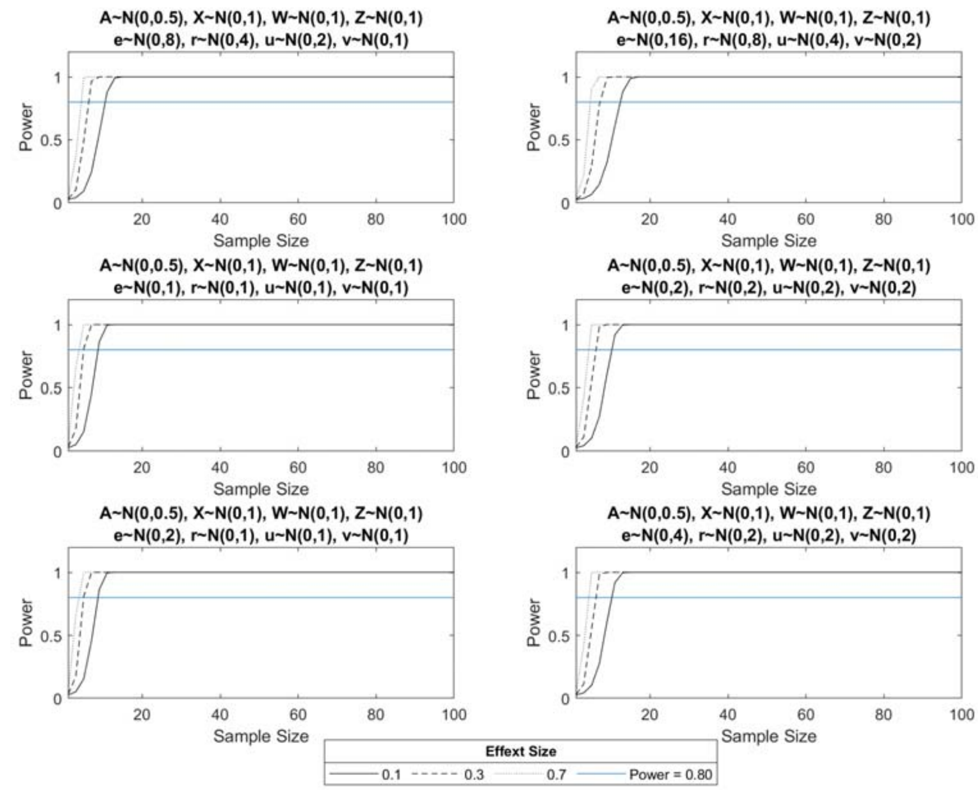

Figure 24. Level-4 HLM power versus sample size plots for intercepts and slopes for Level-3 slope parameter equations ($\delta_{0010}, \delta_{0110}, \delta_{1010}, \delta_{1110}, \delta_{0011}, \delta_{0111}, \delta_{1011}, \delta_{1111}$) with predictor variances $\sigma_A^2 = 0.5$ and $\sigma_X^2 = \sigma_W^2 = \sigma_Z^2 = 1.0$.

($\delta_{0001}, \delta_{0101}, \delta_{1001}, \delta_{1101}, \delta_{0011}, \delta_{0111}, \delta_{1011}, \delta_{1111}$) for $\sigma_A^2 = \sigma_X^2 = \sigma_W^2 = \sigma_Z^2 = 1.0$ (Figure 22), intercepts ($\delta_{1000}, \delta_{1100}, \delta_{1010}, \delta_{1110}$) and slopes ($\delta_{1001}, \delta_{1101}, \delta_{1011}, \delta_{1111}$) for Level-3 intercept parameter equations $\sigma_A^2 = 0.5$ and $\sigma_X^2 = \sigma_W^2 = \sigma_Z^2 = 1.0$ (Figure 23), intercepts ($\delta_{0000}, \delta_{0100}, \delta_{0010}, \delta_{0110}$) and slopes ($\delta_{0001}, \delta_{0101}, \delta_{0011}, \delta_{0111}$) for Level-3 slope parameter equations for $\sigma_A^2 = 0.5$ and $\sigma_X^2 = \sigma_W^2 = \sigma_Z^2 = 1.0$ (Figure 24), pure intercepts ($\delta_{0000}, \delta_{1000}$) for $\sigma_A^2 = 1.0$ and $\sigma_X^2 = \sigma_W^2 = \sigma_Z^2 = 0.5$) (Figure 25), lower level predictors ($\delta_{0100}, \delta_{0010}, \delta_{0001}, \delta_{1100}, \delta_{1010}, \delta_{1001}$) for $\sigma_A^2 = 1.0$, $\sigma_X^2 = \sigma_W^2 = \sigma_Z^2 = 0.5$) (Figure 26, higher level interactions (δ_{0110}, δ_{0101}, δ_{0011}, δ_{1110}, δ_{1101},δ_{1011}) for $\sigma_A^2 = 1.0$ and $\sigma_X^2 = \sigma_W^2 = \sigma_Z^2 = 0.5$ (Figure 27), and large interactions ($\delta_{0111}, \delta_{1111}$) for $\sigma_A^2 = 1.0$ and $\sigma_X^2 = \sigma_W^2 = \sigma_Z^2 = 0.5$ (Figure 28). Again, these figures demonstrate sufficient power at decreasing sample sizes per level. Further the differences in power between low estimated

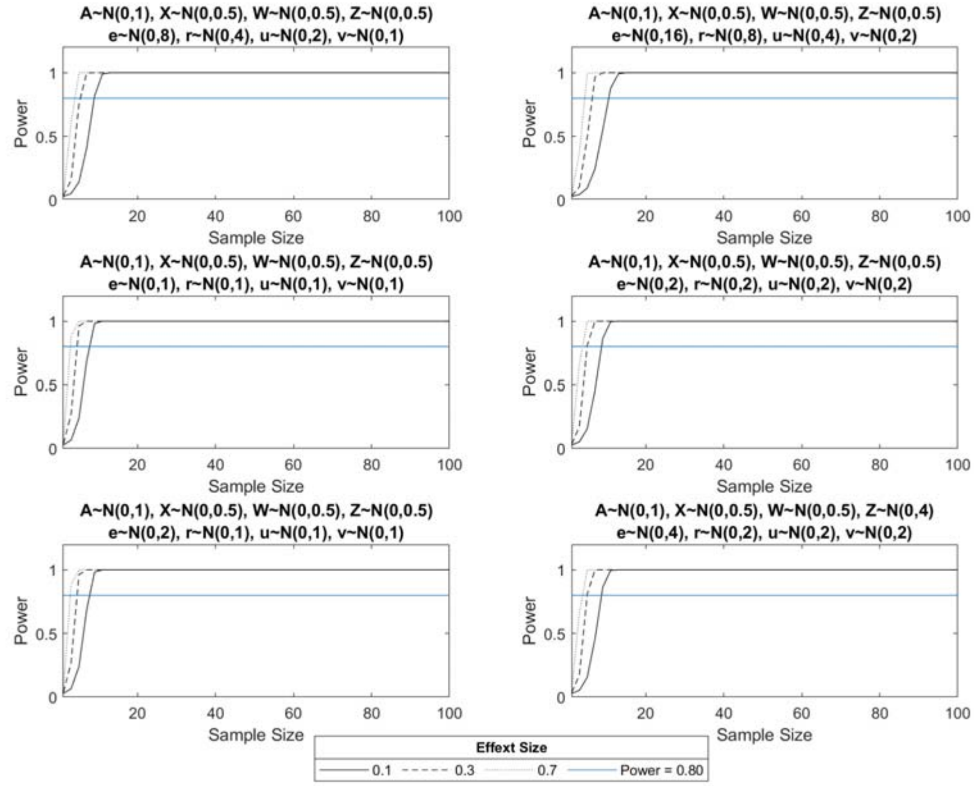

Figure 25. Level-4 HLM power versus sample size plots for pure intercepts (δ_{0000},δ_{1000}) with predictor variances $\sigma_A^2 = 1.0$ and $\sigma_X^2 = \sigma_W^2 = \sigma_Z^2 = 0.5$.

effect size (0.1) and higher estimated effect sizes (0.3, 0.7) diminished as the number of levels increased.

The specific sample size recommendations to achieve at least 0.80 power for $n = g = h = f$ and the smallest sample size set (n, g, h, f) for each predictor and error distribution are outlined in Table 13. The smallest sample size set refers to the set in which the smallest value for Level-1, Level-2, Level-3, or Level-4 is found that results in at least 80% power. That is, numbers within the (n, g, h, f) set are interchangeable between levels and are conventionally listed smallest to largest. For comparison, this research associates the first number, n, with Level-1, the second number, g, with Level-2, the third number, h, with Level-3, and the fourth number, f, with Level-4.

Comparing previous Level-2 sufficient sample sizes at each level for a minimum power of 0.80 to Level-4 sufficient sample sizes has not been done in previous studies. This research

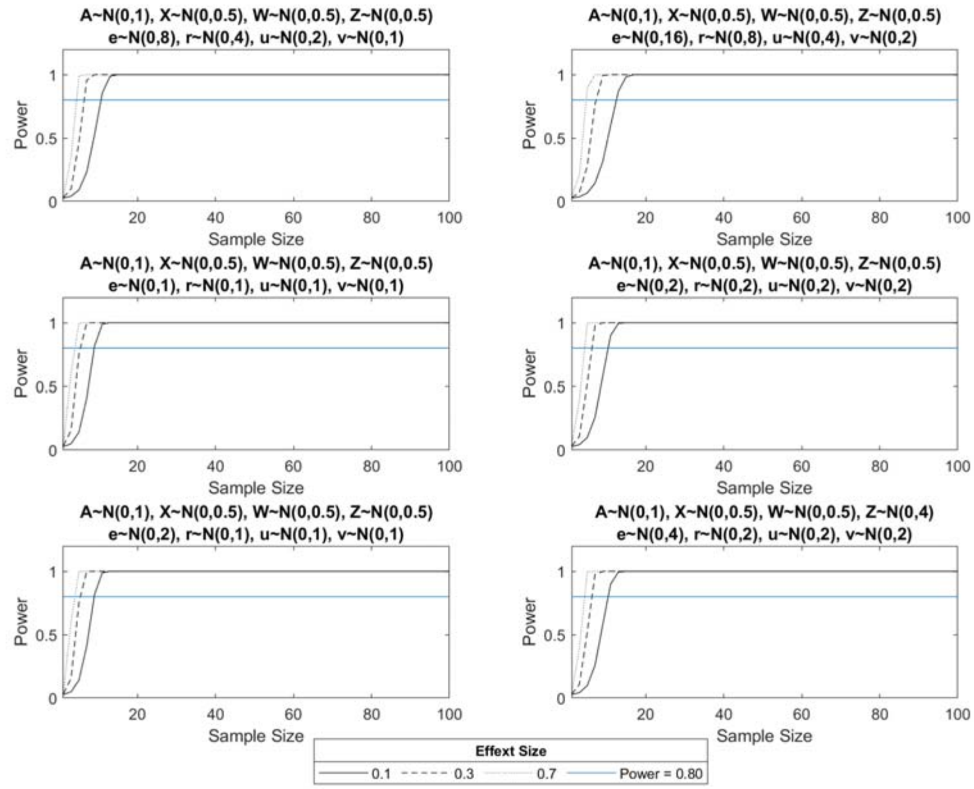

Figure 26. Level-4 HLM power versus sample size plots for lower level predictors (δ_{0100},$\delta_{0010}, \delta_{0101}, \delta_{11000}, \delta_{1010}, \delta_{1001}$) with predictor variances $\sigma_A^2 = 1.0$ and $\sigma_X^2 = \sigma_W^2 = \sigma_Z^2 =$ 0.5.

extended the general rule of thumb of 30 samples at each level to the 3rd-level and 4th-level of a Level-4 HLM and in Table 13 provides the exact sample size requirements to achieve at least 0.80 power in parameter testing. For different estimated effect sizes this research found that when the predictor and error variance at Level-1, Level-2, Level-3, and Level-4 equals 1.0 ($\sigma_A^2 = \sigma_X^2 = \sigma_W^2 = \sigma_Z^2 = \sigma_e^2 = \sigma_r^2 = \sigma_u^2 = \sigma_v^2 = 1.0$) the assumption of 30 samples at Level-1, Level-2, Level-3, and Level-4 to achieve a minimum power of 0.80 was an overestimate because the minimum number of samples at each level was found to be 10, 6, and 5 sample sizes per level for estimated effect size 0.1, 0.3, and 0.7, respectively, much fewer than the general rule (Table 13).

Similar to Level-2 and Level-3 HLM, for all Level-4 HLM predictor and error variance scenarios, as the estimated effect size (0.1, 0.3, 07) increased the number of samples for

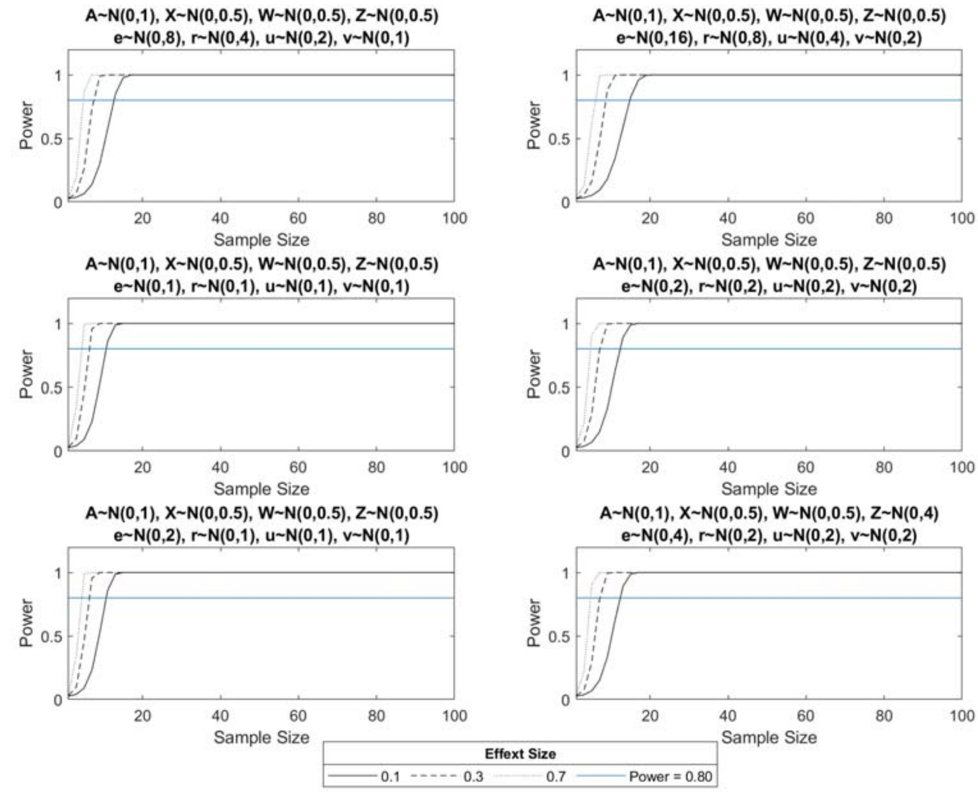

Figure 27. Level-4 HLM power versus sample size plots for higher level interactions ($\delta_{0110}, \delta_{0101}, \delta_{0011}, \delta_{1110}, \delta_{1101}, \delta_{1011}$) with predictor variances $\sigma_A^2 = 1.0$ and $\sigma_X^2 = \sigma_W^2 = \sigma_Z^2 =$ 0.5.

each level to achieve a minimum power of 0.80 decreased. For example, in Table 13 and Figure 22, the Level-4 HLM intercepts ($\delta_{0000}, \delta_{0100}, \delta_{1100}, \delta_{0010}, \delta_{0110}, \delta_{1010}, \delta_{1110}$) and slopes ($\delta_{0001}, \delta_{0101}, \delta_{1001}, \delta_{1101}, \delta_{0011}, \delta_{0111}, \delta_{1011}, \delta_{1111}$) with predictor variances $\sigma_A^2 = \sigma_X^2 = \sigma_W^2 = \sigma_Z^2 = 1.0$, and error variances $\sigma_e^2 = 2$, $\sigma_r^2 = \sigma_u^2 = \sigma_v^2 = 1.0$ required 10, 6, and 5 samples at Level-1, Level-2, Level-3, and Level-4 when $n = g = h = f$ for estimated effect sizes 0.1, 0.3, and 0.7, respectively. In other words, estimated effect size 0.7 required 5 fewer samples per level than estimated effect size 0.1. Also, if the smallest set of (n, g, h, f) is considered, then the associated sample size sets are (3,11,17,17), (1,1,13,90), and (1,1,7,45) at Level-1, Level-2, Level-3, and Level-4 for estimated effect sizes 0.1, 0.3, and 0.7, respectively. With unequal sample sizes, estimated effect size 0.7 requires fewer overall sample sizes than estimated effect size 0.1 to achieve a minimum power of 0.80.

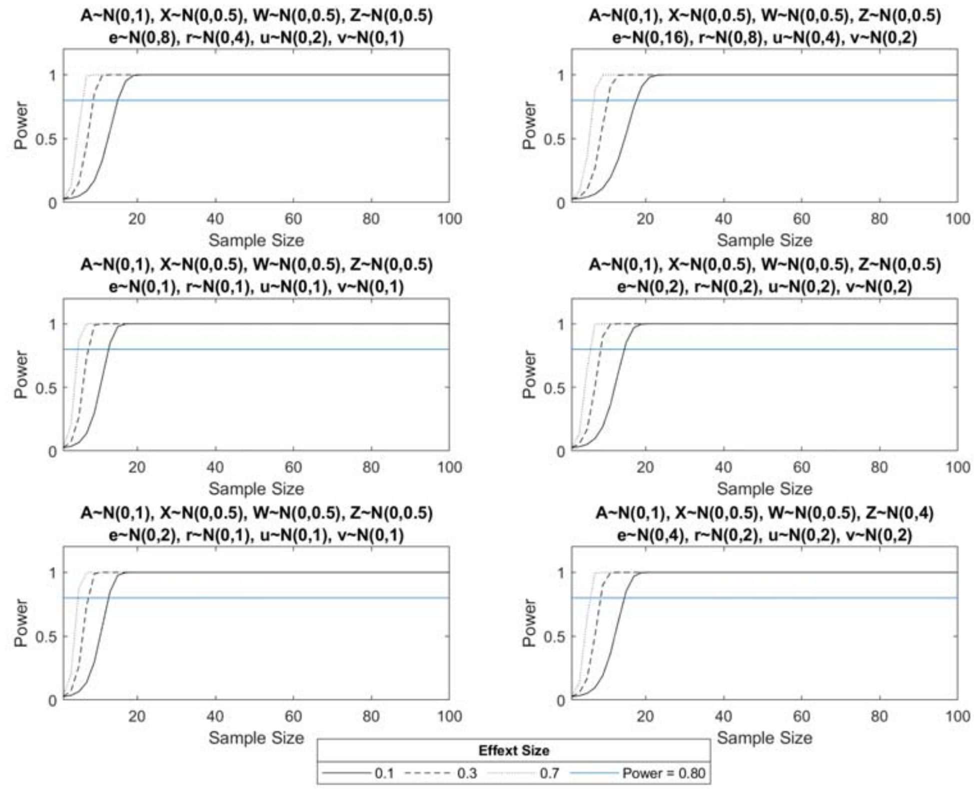

Figure 28. Level-4 HLM power versus sample size plots for large interactions (δ_{0111},δ_{1111}) with predictor variances $\sigma_A^2 = 1.0$ and $\sigma_X^2 = \sigma_W^2 = \sigma_Z^2 = 0.5$.

That is (n, g, h, f) requires an increase of 2 (for n), 10 (for g), 10 (for h), and 28 (for f). Notice once again, that the highest differences are in the higher levels by convention.

As the error variance values double (Table 10: Case 1 versus Case 2) for all Level-4 HLM predictor and error variance scenarios, the sample sizes needed per level increased to achieve a minimum power of 0.80. This is demonstrated in Figures 22 to 28 when comparing the left-hand side to the right-hand side. For example, for the Level-4 HLM large interactions $(\delta_{0111}, \delta_{1111})$ with predictor variances $\sigma_A^2 = 1.0$ and $\sigma_X^2 = \sigma_W^2 = \sigma_Z^2 = 0.5$, when the error variance increases from $\sigma_e^2 = 2.0$, $\sigma_r^2 = \sigma_u^2 = \sigma_v^2 = 1.0$ to $\sigma_e^2 = 4.0$, $\sigma_r^2 = \sigma_u^2 = \sigma_v^2 = 2.0$ the number of samples at Level-1, Level-2, Level-3, and Level-4 when $n = g = h = f$ requires 3, 2, and 0 more samples per a level for estimated effect sizes 0.1, 0.3, and 0.7, respectively, to achieve a minimum power of 0.80 (Table 5 and Figure 28).

As the error variance at Level-1, σ_e^2, increased, for all Level-4 HLM predictor variances

considered, the sample sizes required to achieve a minimum power of 0.80 stayed the same or increased by 1 sample size per a level for the estimated effect sizes considered (Table 10 and Figures 22 to 28). For example, consider the Level-4 HLM large interactions $(\delta_{0111}, \delta_{1111})$ with predictor variances $\sigma^2_A = 1.0$ and $\sigma^2_X = \sigma^2_W = \sigma^2_Z = 0.5$, and error variances $\sigma^2_r = \sigma^2_u = \sigma^2_v = 1.0$. When the Level-1 error variance doubles from $\sigma^2_e = 1.0$ to $\sigma^2_e = 2.0$ the number of samples at Level-1, Level-2, Level-3, and Level-4 when $n = g = h = f$ required no sample size change per a level for estimated effect sizes 0.1, 0.3, and 0.7, respectively, to achieve minimum power of 0.80. Though, the smallest set (n, g, h, f) requires a difference of (0,10,10,8), (0,0,0,10), and (0,0,2,0) for estimated effect sizes 0.1, 0.3, and 0.7, respectively. This implies that even though the number of sample sizes per a level vary, the sample sizes required per a level do not change due to rounding (Table 10 and Figure 28).

As the predictor variance at Level-1, σ^2_A, decreases from 1.0 to 0.5, the sample sizes required stay the same or minimally increases for all estimated effect sizes for the intercepts and slopes $(\delta_{0000}, \delta_{0100}, \delta_{0010}, \delta_{0110}, \delta_{0001}, \delta_{0101}, \delta_{0011}, \delta_{0111})$ of the Level-3 slope parameter equations and stays the same or minimally decreases for all estimated effect sizes for intercepts and slopes $(\delta_{1000}, \delta_{1100}, \delta_{1010}, \delta_{1110}, \delta_{1001}, \delta_{1101}, \delta_{1011}, \delta_{1111})$ of the Level-3 intercept equations (Table 10 and Figures 23 to 24). For example, for the Level-4 HLM intercepts and slopes with predictor variances $\sigma^2_A = \sigma^2_X = \sigma^2_W = \sigma^2_Z = 1.0$, and error variances $\sigma^2_e = 1.0 = \sigma^2_r = \sigma^2_u = \sigma^2_v = 1.0$, compared to Level-1 predictor variance $\sigma^2_A = 0.5$ for the intercepts and slopes of the Level-3 slope parameter equations, the number of samples at Level-1, Level-2, and Level-3 for equal sample sizes $(n = g = h = f)$ required an increase of 1, 1, and 0 samples per level for estimated effect sizes 0.1, 0.3, and 0.7, respectively (Table 10, and Figure 22 and 24). Whereas, to achieve a minimum power of 0.80 when predictor variances $\sigma^2_A = \sigma^2_X = \sigma^2_W = \sigma^2_Z = 1.0$ and error variances $\sigma^2_e = \sigma^2_r = \sigma^2_u = \sigma^2_v = 1.0$ compared to Level-1 predictor variance $\sigma^2_A = 0.5$ for the intercepts and slopes of the Level-3 intercept parameter equations, the number of required samples at Level-1, Level-2, Level-3, and Level-4 for equal sample sizes $(n = g = h = f)$

requires 1, 0, 1 fewer sample sizes per level effect 0.1, 0.3, and 0.7, respectively (Table 10, and Figure 22 and 23).

As the predictor variance at Level-2, Level-3, and Level-4, X_{ijkl}, W_{ijkl} and Z_{ijkl}, decreased from 1.0 to 0.5, the sample sizes required per level generally stayed the same or increased for all estimated effect sizes for large lower level predictors ($\delta_{0100}, \delta_{0010}, \delta_{0001}, \delta_{1100}, \delta_{1010}, \delta_{1001}$), higher level interactions (δ_{0110}, δ_{0101}, δ_{0011}, δ_{1110}, δ_{1101},δ_{1011}), and large interactions ($\delta_{0111}, \delta_{1111}$) (Table 10 and Figures 26 to 28) and stayed the same or decreased for pure intercepts ($\delta_{0000}, \delta_{1000}$). For example, for the Level-4 HLM intercepts and slopes with predictor variances $\sigma_A^2 = \sigma_X^2 = \sigma_W^2 = \sigma_Z^2 = 1.0$ and error variances $\sigma_e^2 = \sigma_r^2 = \sigma_u^2 = \sigma_v^2 = 1.0$, compared to large interactions with predictor variances $\sigma_X^2 = \sigma_W^2 = \sigma_Z^2 = 0.5$, the number of samples at Level-1, Level-2, Level-3, and Level-4 when $n = g = h = f$ required 5, 3, and 1 more samples per a level for effects sizes 0.1, 0.3, and 0.7, respectively (Table 10 and Figures 22 to 28). Whereas, when the same scenario was compared to pure intercepts with predictor variances $\sigma_X^2 = \sigma_W^2 = \sigma_Z^2 = 0.5$, the number of samples at Level-1, Level-2, Level-3, and Level-4 when $n = g = h = f$ required 1, 1, and 1 fewer samples per a level for effects sizes 0.1, 0.3, and 0.7, respectively (Table 10 and Figures 22 to 28).

In general, Level-4 HLM sample size criteria assumptions are similar to Level-2 and Level-3 conclusions. For a Level-4 HLM to achieve sufficient power of 0.80 for different estimated effect sizes this research found that:

- The general rule of thumb was an over estimate for the Level-4 HLM sample size requirements. 30 samples at Level-1 and Level-2 did not extend to Level-4. Low estimated effect sizes (e.g., 0.1) required 10 sample sizes at each level and higher estimated effect sizes (0.3 and 0.7), required 6 and 5 sample sizes at each level, respectively.

- As the estimated effect size (0.1, 0.3, 07) increased for all Level-4 parameters (δ_{0000},δ_{0100},δ_{1000},δ_{1100},δ_{0010},δ_{0110},δ_{1010},δ_{1110},δ_{0001},δ_{0101},δ_{1001},δ_{1101},δ_{0011},δ_{0111},δ_{1011},δ_{1111})

the number of samples required per level decreased.

- When error variance $(\sigma_e^2, \sigma_r^2, \sigma_u^2, \sigma_v^2)$ values double (Figures 22 to 28 right-hand side compared to left-hand-side) for all Level-4 parameters the sample sizes needed per level increased.

- When the error variance at Level-1, σ_e^2, increased, the sample sizes required do not change for all estimated effect sizes.

- As the predictor variance at Level-1, σ_A^2, decreases from 1.0 to 0.5, the sample sizes required generally did not change or minimally increases for intercepts and slopes of the Level-3 slope parameter equations, and did not change or minimally decreased for intercepts and slopes of the Level-3 intercept parameter equations.

- When the predictor variances at Level-2, Level-3, and Level-4, σ_X^2, σ_W^2, and σ_Z^2, decreases from 1.0 to 0.5, the sample sizes required per level generally increases for lower level predictors, higher level predictors, and large interactions, while minimally decreasing for pure intercepts.

For this Level-4 HLM simulation, all sample size tables for every combinations within the simulation is provided in Appendix B.4.

Summary.

The associated level error variances were chosen based on realistic operational distributions where the variability of individuals at Level-1 is greater than or equal to the variability of groups, units, and organizations at higher levels (Level-2, Level-3, and Level-4, respectively). The error variance assumptions and variance terms were chosen similar to literature of Level-2 HLM analysis such that the ICC values were generally moderate and largest at the lowest level. In general, for the five simulation scenarios outlined for the Level-2, Level-3, and Level-4 HLMs, this research found the increases and decreases in sample sizes required per level of Level-2, Level-3 and Level-4 to be similar to achieve a minimum power of 0.80.

For the Level-2 general rule of thumb, 30 sample sizes per Level-1 and Level-2 to achieve sufficient power was not met for estimated effect size 0.1, but for higher estimated effect sizes (0.3 and 0.7) when 30 sample sizes per level was considered, the minimum samples required at each level was almost half (17 sample sizes per level). When the rule of thumb was extended to Level-3 and Level-4 the samples per level to achieve minimum sufficient power of 0.80 was an overestimate for all estimated effect sizes considered (0.1, 0.3, and 0.7). Therefore, for the scenarios considered, the general rule of thumb is an overestimate for the larger estimated effect sizes considered (0.3 and 0.7) and should not be extended to higher levels of HLM analysis.

As the estimated effect sizes increased, from 0.1 to 0.7, for all predictor and error variance scenarios considered, the number of sample sizes required per each level decreased to achieve minimum power of 0.80 for the Level-2, Level-3, and Level-4 HLMs. When error variances for all levels of the Level-2, Level-3 and Level-4 HLMs were doubled, the sample sizes needed per level to achieve minimum power of 0.80 increased. Previous literature did not increase the error variance terms, rather for Level-2 HLM analysis, literature kept Level-1 error variance consistent, $\sigma_e^2 = 1.0$ and changed σ_r^2 based on the assumed ICC values. As stated previously, this research used the error variance information rather than the ICC values because information about the ICC values would not be known, but information about the error variances for each level could be.

When the error variance at Level-1, σ_e^2, increased, the sample sizes required to achieve minimum power of 0.80 in general increased. Therefore, if the only difference between two organizations is the individual or analyst (e.g., Level-1), then a novice analysts' contributions to the organization (Level-4) can impact power and sample sizes needed to achieve a minimim power of 0.80.

Similarly, if the predictor variance at Level-1, σ_A^2, decreases from 1.0 to 0.5, the sample sizes required per level to achieve a minimum power of 0.80 did not change or minimally increased for the previous level slope parameter equations (i.e., for Level-4 HLM analysis, the Level-3 slope parameter equations) and did not change or minimally decreased for the

previous level intercept parameter equations (i.e., for Level-4 HLM analysis, the Level-3 intercept parameter equations). That is as the variability of the work or tasking distribution decreased at Level-1, the samples required to assess the HLM increased for slope parameters and decreased for intercept parameters. As the predictor variances decreases from 1.0 to 0.5 for higher levels, $\sigma_X^2, \sigma_W^2, \sigma_Z^2$, the sample sizes required per level to achieve a minimum power of 0.80 depended on the parameters of interest. As the variability of the work or tasking distributions decreased for Level-2, Level-3, and Level-4 HLMs the number of sample sizes required per level was important when sample sizes are an issue.

Thus, the number of sample sizes required to achieve minimum power of 0.80 changes based estimated effect size, and predictor and error variability assumption. If the number of required sample sizes per level increased, this might not always be achievable due to population limitations, cost, and analyst accessability. Therefore, sample size re-sampling techniques are considered to achieve minimum sufficient power of 0.80 in Research Objective 2 for such cases.

IV. Research Objective 2: Re-Sampling Small Sample Size Based Method

4.1 Re-Sampling Hierarchical Linear Model (HLM) Recommendations for the Effects on Parameter Estimation with Insufficient Power in Level-2 and Level-3 HLM

To achieve the goal of Research Objective 2, the power results and procedures of Research Objective 1 for Level-2 and Level-3 HLMs are applied to operationally realistic small sample size combinations for estimation and detailed in Table 14. The small sample size combinations considered reflect achievable samples per each level based on cost and prior access to small operational populations. However, these sample sizes generally did not achieve sufficient power for specific scenarios even for high effect sizes. Using the combined Level-2 and Level-3 HLM measurement models specified in Chapter 2, and the five simulation conditions outlined in Chapter 3, these associated parameters of the HLM measurement models that did not achieve a minimum power of 80% were re-sampled to larger sample sizes. For a Level-2 HLM, the extended sample sizes considered at both Level-1 and Level-2 were 30, 50, 100, 200, and 500. For a Level-3 HLM, the extended sample sizes considered at both Level-1, Level-2, and Level-3 were 30, 50, 100 and 200 (for effect size 0.3 and 0.7 only). Assessment and re-sampling method recommendations are provided for the effects on parameter estimation, parameter bias, and power in the subsection Re-Sampling HLM Recommendations.

In general, the re-sampling procedure proceeded as follows. For each sample size considered in Table 14 that did not meet minimum sufficient power of 0.80, a random draw was generated for each scenario as given in Chapter III (i.e., $\sigma_A^2 = \sigma_X^2 = \sigma_e^2 = \sigma_r^2 = 1.0$ is a scenario). These observed data for the random draw were used to estimate predictor $(A_{ijk}, X_{ijk}, W_{ijkl})$ and error $(e_{ijk}, r_{ijkl}, u_{ijk})$ distributions. Then from these estimated distributions, samples of size 30, 50, 100, and 200 were drawn and REML used to estimate the HLM. This process was repeated 1,000 times and the accuracy of the parameter

estimated as well as power to detect if the estimates significantly differ from zero was calculated across the 1,000 replicates. Specific details are provided in subsequent sections for the Level-2 and Level-3 HLM.

Table 14. Level-2 and Level-3 HLM small sample size combinations considered by level for larger sample size re-sampling

Parameter Accuracy.

Parameter accuracy is determined using bias. If a parameter has zero bias, then it is called unbiased and there is no difference between the parameter's expected value ($\hat{\mu}$) and the true value being estimated (μ). The expected bias of a parameter decreases with larger sample sizes. The accuracy of the parameter estimates is indicated by the absolute relative bias. Since $\hat{\mu}$ is the estimate of the population parameter μ, the absolute relative bias is

$$\left|\frac{\hat{\mu} - \mu}{\mu}\right|. \tag{31}$$

That is, the absolute relative bias for the Level-2 parameters is

$$\left|\frac{\hat{\beta}_{ij} - \beta_{ij}}{\beta_{ij}}\right|, \tag{32}$$

and the absolute relative bias for the Level-3 parameters is

$$\left|\frac{\hat{\gamma}_{ijk} - \gamma_{ijk}}{\gamma_{ijk}}\right|. \tag{33}$$

Simulation Run Time.

Recall to examine the effects of re-sampling on parameter estimation and model specification for each of the HLM levels considered (Level-2 and Level-3), 1000 Monte Carlo simulation were conducted using the multilevel Matlab toolbox, linear mixed-effects model (lme), to estimate the parameters and generate the simulated data [29]. The coefficients were estimated using the Maximum Likelihood function REML within Matlab.

The computation time to complete each iteration exponentially increased by level and re-sampled sample sizes considered as shown in Table 15. For example, to re-sample each level of a Level-2 HLM small sample combinations to a sample size of 30 ($N = 30$ individuals x 30 groups = 900) takes 56,000 seconds to complete 1,000 Monte Carlo iterations across all scenarios for each small sample size combination that did not have a minimum sufficient power of 0.80. Whereas, to re-sample each level of a Level-3 HLM small sample combinations to a sample size of 30 ($N = 30$ individuals x 30 groups x 30 units = 27,000) takes 672,000 seconds to complete 1,000 Monte Carlo iterations across all scenarios for each small sample size combination that did not have a minimum sufficient power of 0.80.

Table 15. Small sub sample re-sampled to larger sample sizes run times by level in seconds (sec).

Level	Re-Sampled Sizes per level	Run Time sec	Number of Runs	Total Time (sec) x Number of Monte Carlo runs
Level-2	30	0.25	224	56,000
	50	0.50	224	112,000
	100	0.50	224	112,000

Level-2 Re-Sample Based HLM Recommendations.

For the Level-2 HLM the scenario conditions considered were: small sample sizes at each level (8 total as shown in Figure 14), effect size (0.1, 0.3, 0.7), Level-1 initial variance ($\sigma_e^2 = 1.0, 2.0$), error term distributions by level (2 cases as shown in Table 2), and predictor distributions by level (3 cases as shown in Table 3). Of the 8 x 3 x 2 x 2 x 3 = 288 scenarios considered, 224 scenarios did not reach a minimum power of 0.80 from the previous chapter results (Appendix B.1). Thus, these 224 scenarios were extended to the larger sample sizes 30, 50, 100, 200, and 500 for each level as described. The specific conditions are listed in Table 16. As previously described for each scenario, 1000 Monte Carlo simulations were performed and the associated average power (Tables 17 to 19 and Figure 29 to 32) and average relative bias (Tables 20 to 22 and Figure 33 to 36) were reported.

Table 16. Level-2 small sample sizes by level that did not have a minimum power of 0.80.

	Sample Size By Level			Predictor Distributions		Error Variance Distributions

The Level-2 intercept parameters (β_{00} Figure 29 and β_{10} Figure 30) with small sample sizes and initial error variance $\sigma_e^2 = 1.0$ that did not have a minimum sufficient power of

0.80 (Table 16), achieved sufficient power when re-sampled to 30 samples at each level for large effect size 0.7 (Tables 17 to 19 and Figure 29 and 30: left-hand side in green), and for initial error variance $\sigma_e^2 = 2.0$ less than 30 re-sampled samples at each level for effect size 0.7 (Tables 17 to 19 and Figure 29 and 30: right-hand side in green).

For medium effect size 0.3 (Figures 29 to 32: in blue), the Level-2 intercept parameters achieved minimum sufficient power of 0.80 when re-sampled to 200 samples at each level for initial error variance $\sigma_e^2 = 1.0$ (Tables 17 to 19 and Figures 29 and 30: left-hand side in blue) and 100 re-sampled samples at each level for initial error variance $\sigma_e^2 = 2.0$ (Tables 17 to 19 and Figures 29 and 30: right-hand side in blue).

The Level-2 intercept parameters with small sample sizes that did not have a minimum power of 0.80 still did not achieve minimum sufficient power for small effect size 0.1 and initial error variance $\sigma_e^2 = 1.0$ and 2.0 (Tables 17 to 19 and Figure 29 and 30: in black). When small sample sizes were re-sampled to 500 samples at each level, the maximum power for Level-2 intercept parameters was around 0.60. Similar to the Level-2 intercept parameters, the Level-2 slope parameters (β_{01} Figure 31 and β_{11} Figure 32) with small sample sizes and initial error variance $\sigma_e^2 = 1.0$ that did not have a minimum sufficient power of 0.80 (Table 16), achieved sufficient power when re-sampled to 100 samples at each level for large effect size 0.7 (Tables 17 to 19 and Figure 31 and 32: left-hand side in green). The Level-2 slope parameter re-sampled sample size per level to achieve minimum power of 0.80 was 70 sample sizes greater for each level than the Level-2 intercept parameters. For initial error variance $\sigma_e^2 = 2.0$ and predictor variances $\sigma_A^2 = \sigma_X^2 = 1.0$ and $\sigma_A^2 = 0.5, \sigma_X^2 = 1.0$, 30 re-sampled sample sizes at each level for effect size 0.7 were required for sufficient power of 0.80, and for $\sigma_A^2 = 1.0, \sigma_X^2 = 0.5$, 50 re-sampled samples at each level for effect size 0.7 (Tables 17 to 19 and Figure 31 and 32: right-hand side in green).

For medium effect size 0.3, the Level-2 slope parameters achieved minimum sufficient power of 0.80 when re-sampled to 200 sample sizes at each level for initial error variance $\sigma_e^2 = 1.0, 2.0$, and predictor variances $\sigma_A^2 = \sigma_X^2 = 1.0$ and $\sigma_A^2 = 0.5, \sigma_X^2 = 1.0$. Whereas, 500 re-sampled samples at each level were required for initial error variance $\sigma_e^2 = 1.0$ and

predictor variances $\sigma_A^2 = 1.0, \sigma_X^2 = 0.5$ to achieve sufficient power of 0.80 (Tables 17 to 19 and Figures 31 and 32: left-hand side in blue), and between 200 and 500 re-sampled samples at each level for initial error variance $\sigma_e^2 = 2.0$ (Tables 17 to 19 and Figures 31 and 32: right-hand side in blue). That is, when predictor variance at the team level (Level-2) is considered half, the number of sample sizes per level increased.

The Level-2 slope parameters with small sample sizes that did not have a minimum power of 0.80 still did not achieve minimum sufficient power for small effect size 0.1 and initial error variance $\sigma_e^2 = 1.0$ and 2.0, even when re-sampled to 500 samples at each level (Tables 17 to 19 and Figure 29 and 30: in black).

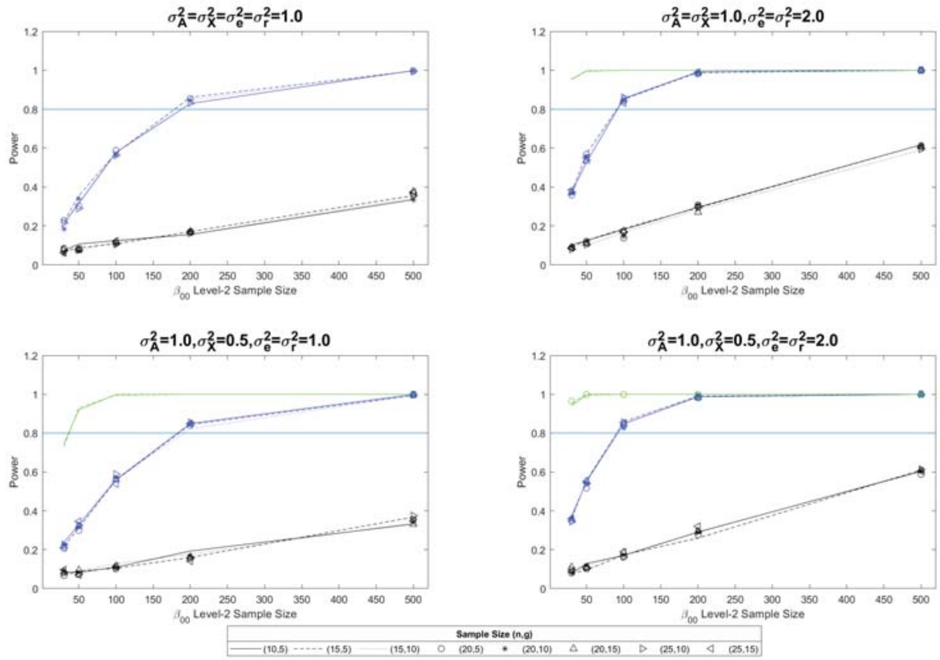

Figure 29. Level-2 β_{00} re-sampled sample size power results for varying effect sizes (0.1 black, 0.3 blue, and 0.7 green) and scenarios $\sigma_A^2 = \sigma_X^2 = 1.0$ (top) and $\sigma_A^2 = 1.0$, $\sigma_X^2 = 0.5$ (bottom) with initial error variance $\sigma_e^2 = \sigma_r^2 = 1$.

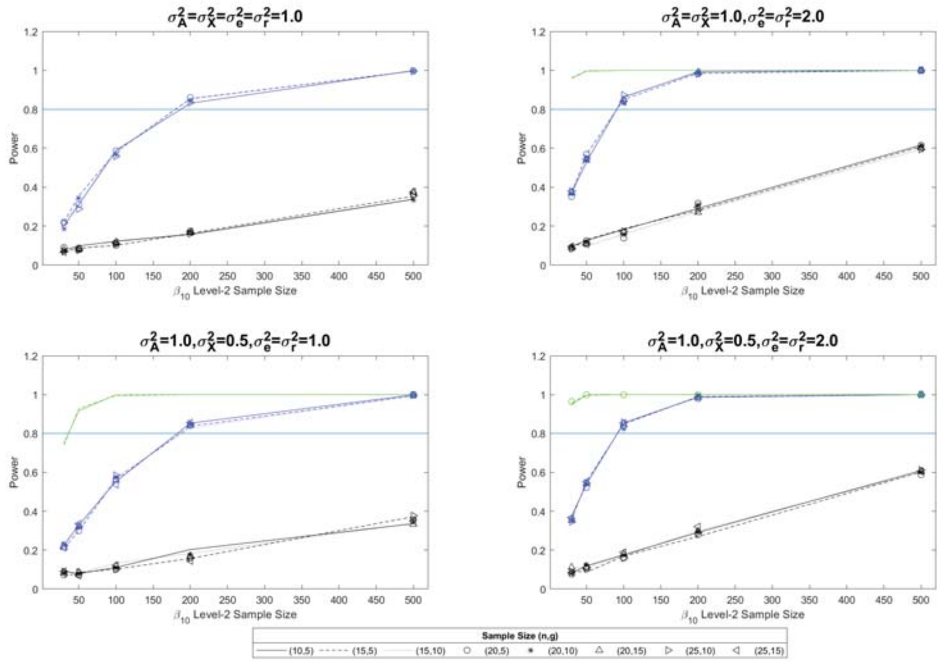

Figure 30. Level-2 β_{10} re-sampled sample size power results for varying effect sizes (0.1 black, 0.3 blue, and 0.7 green) and scenarios $\sigma_A^2 = \sigma_X^2 = 1.0$ (top) and $\sigma_A^2 = 1.0$, $\sigma_X^2 = 0.5$ (bottom) with initial error variance $\sigma_e^2 = \sigma_r^2 = 1$.

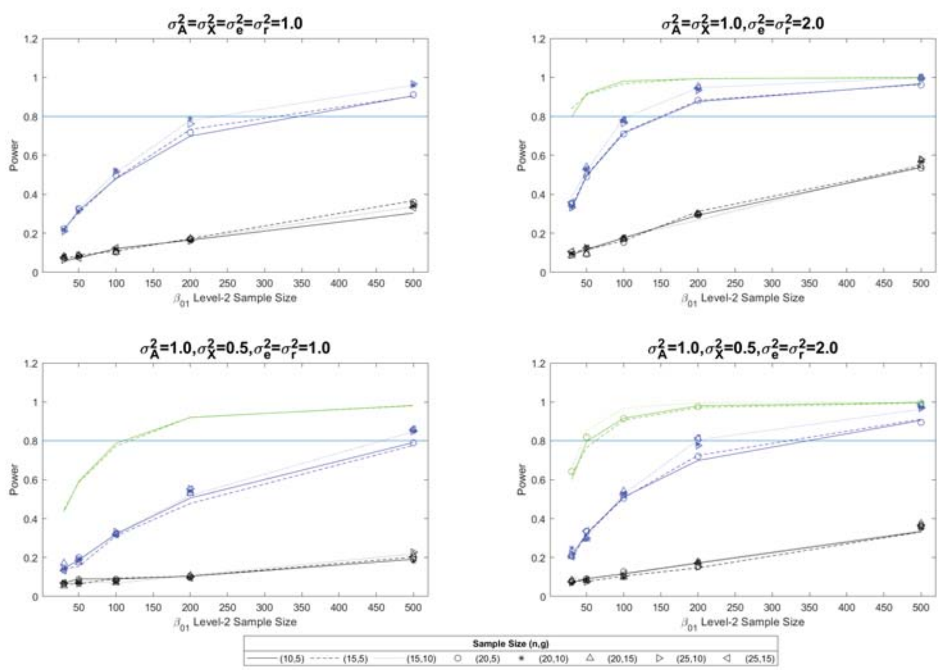

Figure 31. Level-2 β_{01} re-sampled sample size power results for varying effect sizes (0.1 black, 0.3 blue, and 0.7 green) and scenarios $\sigma_A^2 = \sigma_X^2 = 1.0$ (top) and $\sigma_A^2 = 1.0$, $\sigma_X^2 = 0.5$ (bottom) with initial error variance $\sigma_e^2 = \sigma_r^2 = 1$.

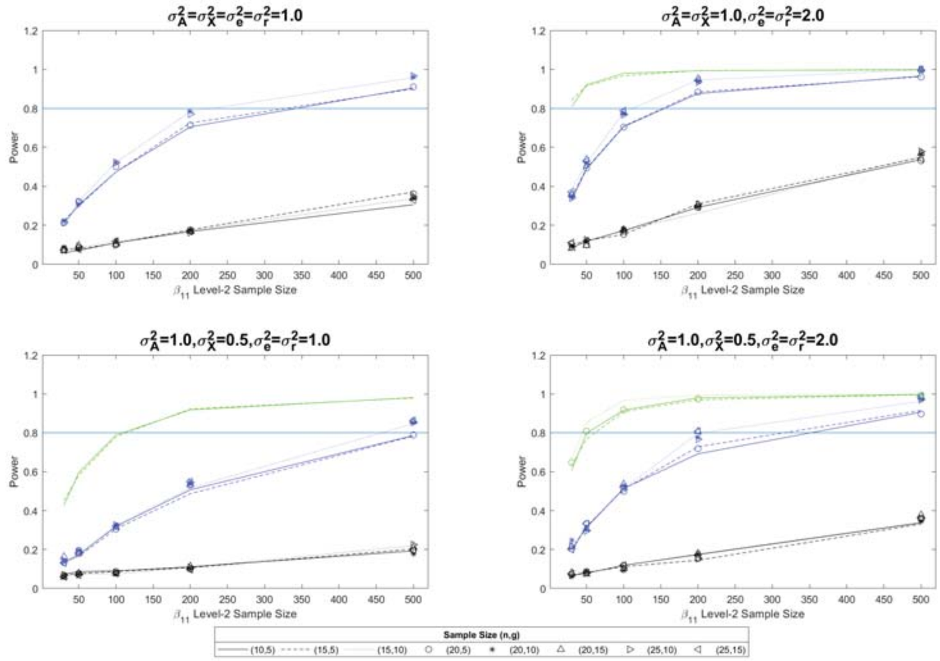

Figure 32. Level-2 β_{11} re-sampled sample size power results for varying effect sizes (0.1 black, 0.3 blue, and 0.7 green) and scenarios $\sigma_A^2 = \sigma_X^2 = 1.0$ (top) and $\sigma_A^2 = 1.0$, $\sigma_X^2 = 0.5$ (bottom) with initial error variance $\sigma_e^2 = \sigma_r^2 = 1$.

Table 17. Average power values for Level-2 parameters based on re-sampled sample sizes for conditions 1 - 75. Minimum power between 0.80 and 0.90 highlighted in light green and greater than 0.90 highlighted in dark green.

Table 19. Average power values for Level-2 parameters based on re-sampled sample sizes for conditions 151 - 224. Minimum power between 0.80 and 0.90 highlighted in light green and greater than 0.90 highlighted in dark green.

		β_{00}					β_{01}					β_{10}					β_{11}

The accuracy of the Level-2 parameter estimates is indicated by the absolute relative bias (Tables 20 to 22 and Figures 33 to 36). As effect size increases from 0.1 to 0.7, the absolute relative bias decreases for all predictor and error variance scenarios considered. For initial error variance $\sigma_e^2 = 1.0$ the absolute relative bias (Figures 33 to 36 left-hand side) is less than initial error variance $\sigma_e^2 = 2.0$ (Figures 33 to 36: right-hand side) and most noticeable for effect size 0.7 (Figures: 33 to 36: shown in green).

Though the Level-2 parameters achieved minimum sufficient power of 0.80 with fewer re-sampled samples at each level for initial error variance $\sigma_e^2 = 2.0$ and effect size 0.3 and 0.7, the associated parameters when re-sampled to larger sample sizes had larger absolute relative bias. Whereas, initial error variance $\sigma_e^2 = 1.0$ required more samples per level, the associated parameters when re-sampled to larger sample sizes had smaller absolute relative bias overall. For example, for initial error variance $\sigma_e^2 = 1.0$, and predictor variances $\sigma_A^2 = 1.0$ and $\sigma_X^2 = 1.0$, the absolute relative bias is about 0.70 (Table: 20 line 56), whereas for initial error variance $\sigma_e^2 = 2.0$ bias is 0.85 (Table: 20 line 58). The specific overall Level-2 parameter average absolute relative bias values by condition, are provided in Tables 20 to 22. The average absolute relative bias remains fairly consistent across re-sampled sample sizes and ranges from about 0.60 to 0.95.

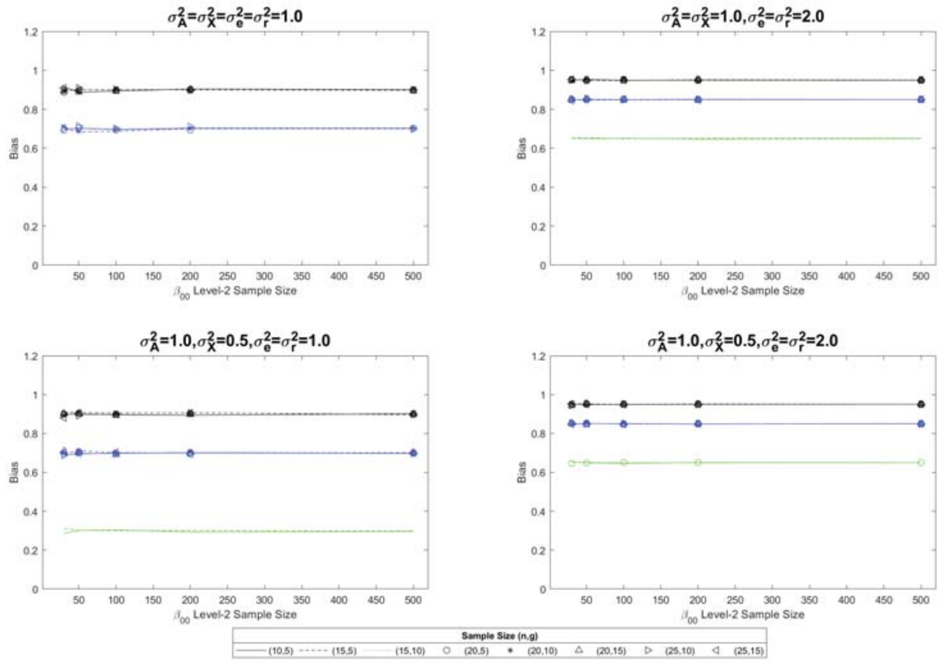

Figure 33. Level-2 β_{00} re-sampled sample size bias results for varying effect sizes (0.1 black, 0.3 blue, and 0.7 green) and scenarios $\sigma_A^2 = \sigma_X^2 = 1.0$ (top) and $\sigma_A^2 = 1.0$, $\sigma_X^2 = 0.5$ (bottom) with initial error variance $\sigma_e^2 = \sigma_r^2 = 1$.

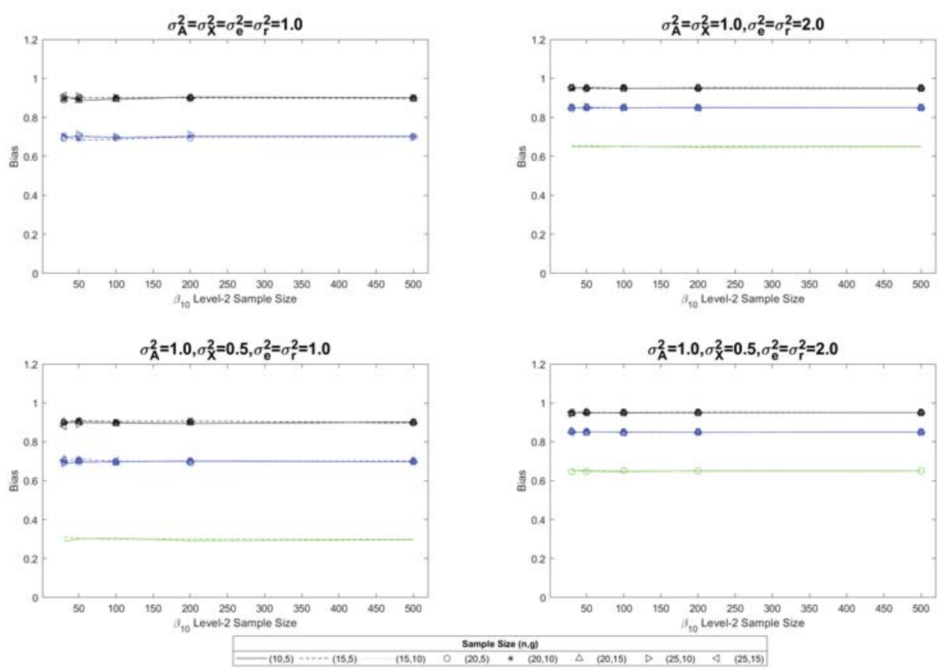

Figure 34. Level-2 β_{10} re-sampled sample size bias results for varying effect sizes (0.1 black, 0.3 blue, and 0.7 green) and scenarios $\sigma_A^2 = \sigma_X^2 = 1.0$ (top) and $\sigma_A^2 = 1.0$, $\sigma_X^2 = 0.5$ (bottom) with initial error variance $\sigma_e^2 = \sigma_r^2 = 1$.

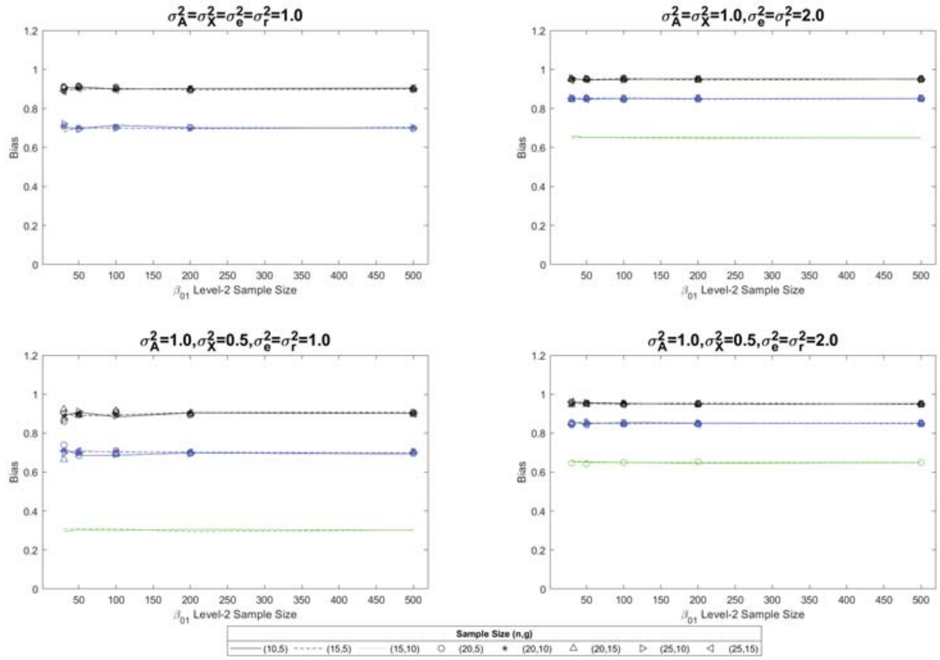

Figure 35. Level-2 β_{01} re-sampeld sample size bias results for varying effect sizes (0.1 black, 0.3 blue, and 0.7 green) and scenarios $\sigma_A^2 = \sigma_X^2 = 1.0$ (top) and $\sigma_A^2 = 1.0$, $\sigma_X^2 = 0.5$ (bottom) with initial error variance $\sigma_e^2 = \sigma_r^2 = 1$.

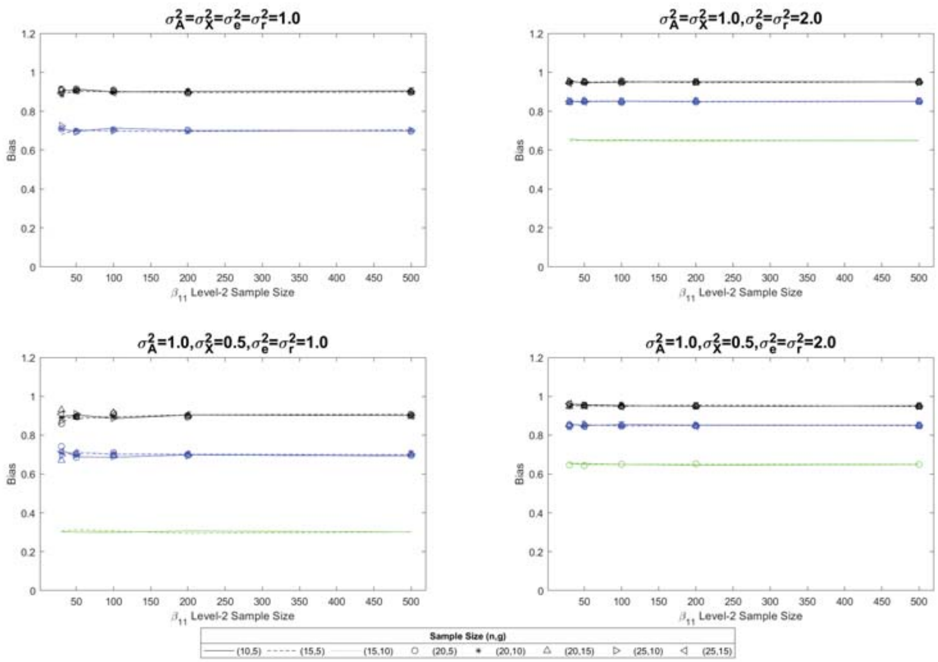

Figure 36. Level-2 β_{11} re-sampled sample size bias results for varying effect sizes (0.1 black, 0.3 blue, and 0.7 green) and scenarios $\sigma_A^2 = \sigma_X^2 = 1.0$ (top) and $\sigma_A^2 = 1.0$, $\sigma_X^2 = 0.5$ (bottom) with initial error variance $\sigma_e^2 = \sigma_r^2 = 1$.

Table 20. Average absolute relative bias values for Level-2 parameters based on the re-sampled sample sizes for conditions 1 - 75.

In general, for a Level-2 HLM with small sample sizes to achieve sufficient power of 0.80 for different effect sizes this research found that:

- For effect size 0.7, Level-2 intercept parameters (β_{00} and β_{10}) with small sample sizes achieved minimum sufficient power of 0.8 when re-sampled to 30 sample sizes per each level with initial error variance $\sigma_e^2 = 1.0$, and less than 30 sample sizes per level with initial error variance $\sigma_e^2 = 2.0$.
- Level-2 slope parameters (β_{01} and β_{11}) with effect size 0.7 and small sample sizes achieved minimum sufficient power of 0.8 when re-sampled to 100 sample sizes per each level with initial error variance $\sigma_e^2 = 1.0$, and 50 sample sizes per level with initial error variance $\sigma_e^2 = 2.0$.
- The intercept parameters with effect size 0.3 and small sample sizes, achieved minimum power of 0.80 when re-sampled to 200 sample sizes per each level with initial error variance $\sigma_e^2 = 1.0$, and 100 sample sizes per each level with initial error variance $\sigma_e^2 = 2.0$.
- Level-2 HLM slope parameters with effect size 0.3 and small sample sizes, achieved minimum power of 0.80 when re-sampled to 200 sample sizes per each level with initial error variance $\sigma_e^2 = 1.0, 2.0$ and predictor variance $\sigma_A^2 = \sigma_X^2 = 1.0$, and $\sigma_A^2 = 1.0, \sigma_X^2 = 0.5$.
- For effect size 0.3, the slope parameters achieved minimum power of 0.80 when re-sampled to 500 sample sizes per each level with initial error variance $\sigma_e^2 = 1.0$ and predictor variance $\sigma_A^2 = 1.0, \sigma_X^2 = 0.5$, and between 200 and 500 sample sizes per each level with inital error variance $\sigma_e^2 = 2.0$.
- Both intercept and slope parameters with effect size 0.1 and initial error variance ($\sigma_e^2 = 1.0, 2.0$) did not achieve minimum sufficient power when re-sampled to 500 sample sizes per each level.

- As effect size increases from 0.1 to 0.7, the bias for all Level-2 parameters decreases for all predictor and error variances considered, and the re-sampled sample size did not affect the overall average absolute relative bias.
- The bias for initial error variance scenarios with $\sigma_e^2 = 1.0$ is less than those with $\sigma_e^2 = 2.0$.
- For the specific scenarios considered, the overall average absolute relative bias ranges from 0.60 to 0.95.

Level-3 Re-Sampling Based HLM Recommendations.

For the Level-3 HLM, the scenario conditions considered were: small sample sizes at each level (8 total as shown in Table 14), effect size (0.1, 0.3, 0.7), Level-1 initial variance ($\sigma_e^2 = 1.0, 2.0$), error term distributions by level (3 cases shown in Table 6), and predictor distributions by level (3 cases shown in Table 3). Of the 8 x 3 x 2 x 3 x 3 = 432 scenarios considered, 236 scenarios did not reach a minimum power of at least 0.80 from the previous chapter results (Appendix B.2). Thus, these 236 scenarios were extended to the larger sample sizes 30, 50, 100, and 200 for each level as described (for effect sizes 0.3 and 0.7, 92 scenario conditions considered). The specific conditions, scenarios, and sample size considerations are listed in Tables 23 and 24. As previously described for each scenario, 1000 Monte Carlo simulations were performed and the associated average power (Tables 25 to 27 and Figure 37 to 44) and average relative bias (Tables 28 to 30 and Figure 45 to 51) were reported.

Table 23. Level-3 small sample sizes by level that did not have a minimum power of 0.80 for conditions 1 - 156.

	Sample Size by Level				Predictor Distribution			Error Variance Distribution		
	Level-1 n	Level-2 g	Level-3 h	Effect Size	Level-1 $N(0,\sigma_A^2)$ σ_A^2	Level-2 $N(0,\sigma_X^2)$ σ_X^2	Level-3 $N(0,\sigma_W^2)$ σ_W^2	Level-1 $N(0,\sigma_e^2)$ σ_e^2	Level-2 $N(0,\sigma_r^2)$ σ_r^2	Level-3 $N(0,\sigma_u^2)$ σ_u^2

The Level-3 intercept parameters ($\gamma_{000}, \gamma_{100}, \gamma_{010}, \gamma_{110}$) with small sample sizes and initial error variance $\sigma_e^2 = 1.0$ that did not have a minimum sufficient power of 0.80 (Tables 23 to 24), achieved sufficient power when re-sampled between 50 to 100 sample sizes at each level for large effect size 0.7 (Tables 25 to 27 and Figures 37,41,39,43): left-hand side in green), and for initial error variance $\sigma_e^2 = 2.0$ 30 re-sampled sample sizes at each level for effect size 0.7 (Tables 25 to 27 and Figures 37,41,39,43): right-hand side in green).

For medium effect size 0.3, the Level-3 intercept parameter γ_{000} (Figure 37: in blue), had an average power of 0.51 and did not achieve minimum sufficient power of 0.80 when re-sampled to 200 samples at each level for initial error variance $\sigma_e^2 = 1.0$ (Tables 25 to 27 and Figure 37: left-hand side in blue). Whereas, the Level-3 intercept parameters $\gamma_{100}, \gamma_{010}, \gamma_{110}, \gamma_{100}$ (Tables 25 to 27 and Figures 41,39,43,41: in blue), achieved sufficient power of 0.80 when re-sampled to 100 sample sizes at each level for initial error variance $\sigma_e^2 = 2.0$.

Similar to the Level-2 intercept parameters, the Level-3 intercept parameters with small sample sizes that did not have a minimum power of 0.80 still did not achieve minimum sufficient power for small effect size 0.1 and initial error variance $\sigma_e^2 = 1.0$ and 2.0 (Tables 25 to 27 and Figures 37,39,49,43: in black). When small sample sizes were re-sampled to 100 sample sizes at each level, the maximum power for Level-3 intercept parameters was less than 0.20.

The Level-3 slope parameters $\gamma_{001}, \gamma_{101}, \gamma_{011}, \gamma_{111}$ with small sample sizes and initial error variance $\sigma_e^2 = 1.0$ that did not have a minimum sufficient power of 0.80 (Tables 25 to 27), had an average power of 0.70 and did not achieve sufficient power when re-sampled to 200 samples at each level for large effect size 0.7 (Tables 25 to 27 and not shown in figures). For initial error variance $\sigma_e^2 = 2.0$ and predictor variances $\sigma_A^2 = \sigma_X^2 = \sigma_W^2 = 1.0$, 200 re-sampled sample sizes at each level for effect size 0.7 were required for sufficient power of 0.80, for predictor variances $\sigma_A^2 = 0.5$ and $\sigma_X^2 = \sigma_W^2 = 1.0$, 50 re-sampled sample sizes at each level for effect size 0.7 were required for sufficient power of 0.80, and for $\sigma_A^2 = 1.0$ and $\sigma_X^2 = \sigma_W^2 = 0.5$, 100 re-sampled sample sizes at each level for effect size 0.7

were required to achieve minimum sufficient power of 0.80. That is, when predictor variance at the team and unit levels (Level-2 and Level-3) is considered half that of the individual level (Level-1), the number of sample sizes per level decreased. And the number of sample sizes required for the re-sampling to achieve sufficient power per level decreased even more when predictor variance at the individual level (Level-1) was considered half that of the team and unit level (Level-2 and Level-3).

For medium effect size 0.3, the Level-3 slope parameters had an average power of 0.75 and did not achieve minimum sufficient power of 0.80 when re-sampled to 200 samples at each level for initial error variance $\sigma_e^2 = 1.0$. Whereas, 200 re-sampled samples at each level were required for initial error variance $\sigma_e^2 = 2.0$ to achieve sufficient power of 0.80 (Tables 25 to 27 and Figures 38,40,42,44: left-hand side in blue).

The Level-2 slope parameters with small sample sizes that did not have a minimum power of 0.80 still did not achieve minimum sufficient power for small effect size 0.1 and initial error variance $\sigma_e^2 = 1.0, 2.0$, even when re-sampled to 200 samples at each level (Tables 25 to 27 and Figures 38,40,42,44: in black).

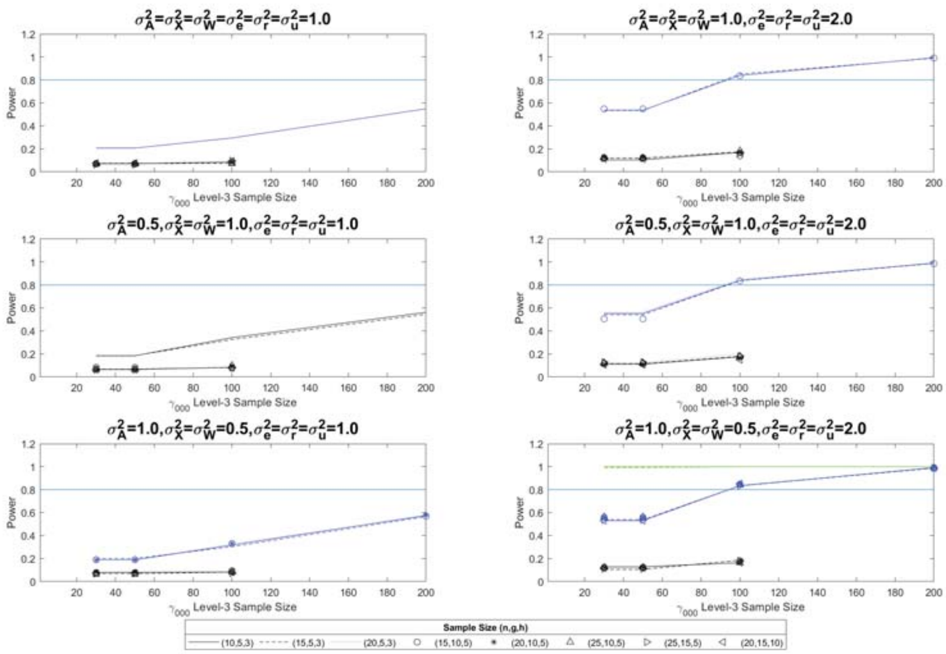

Figure 37. Level-3 γ_{000} re-sampled sample size power results for varying effect sizes (0.1 black, 0.3 blue, and 0.7 green) and scenarios with initial error variance $\sigma_e^2 = \sigma_r^2 = 1$ such that $\sigma_A^2 = \sigma_X^2 = \sigma_X^2 = 1.0$ (top), $\sigma_A^2 = 0.5$, $\sigma_X^2 = \sigma_X^2 = 1.0$ (middle), and $\sigma_A^2 = 1.0$, $\sigma_X^2 = \sigma_X^2 = 0.5$ (bottom).

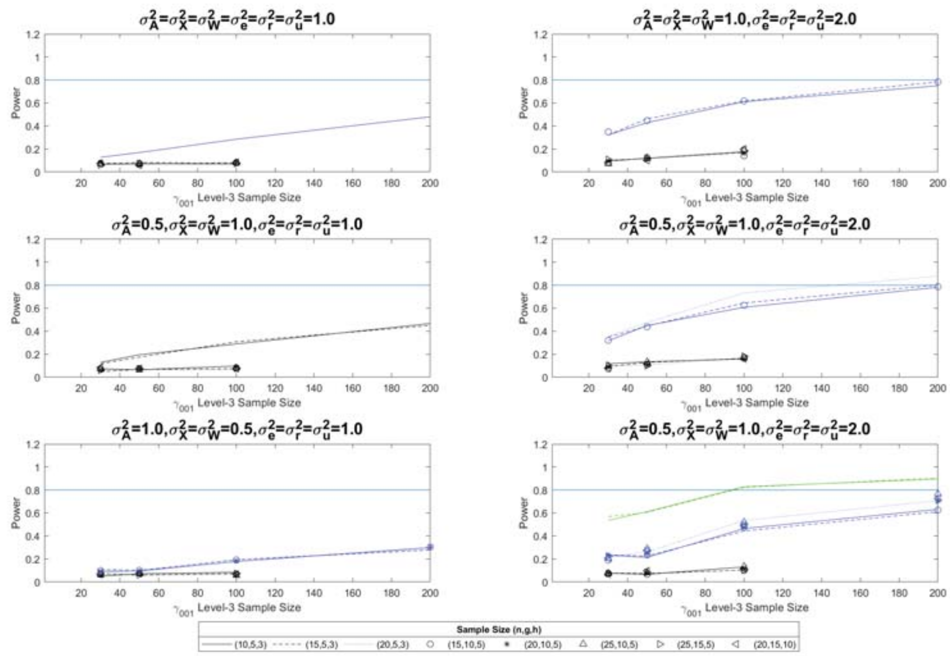

Figure 38. Level-3 γ_{001} re-sampled sample size power results for varying effect sizes (0.1 black, 0.3 blue, and 0.7 green) and scenarios with initial error variance $\sigma_e^2 = \sigma_r^2 = 1$ such that $\sigma_A^2 = \sigma_X^2 = \sigma_X^2 = 1.0$ (top), $\sigma_A^2 = 0.5$, $\sigma_X^2 = \sigma_X^2 = 1.0$ (middle), and $\sigma_A^2 = 1.0$, $\sigma_X^2 = \sigma_X^2 = 0.5$ (bottom).

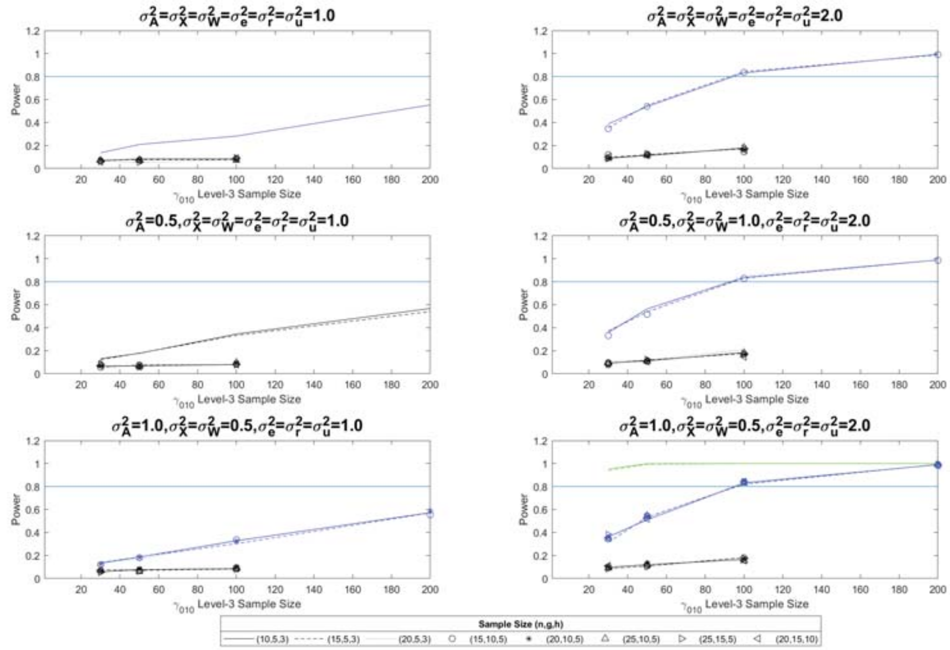

Figure 39. Level-3 γ_{010} re-sampled sample size power results for varying effect sizes (0.1 black, 0.3 blue, and 0.7 green) and scenarios with initial error variance $\sigma_e^2 = \sigma_r^2 = 1$ such that $\sigma_A^2 = \sigma_X^2 = \sigma_X^2 = 1.0$ (top), $\sigma_A^2 = 0.5$, $\sigma_X^2 = \sigma_X^2 = 1.0$ (middle), and $\sigma_A^2 = 1.0$, $\sigma_X^2 = \sigma_X^2 = 0.5$ (bottom).

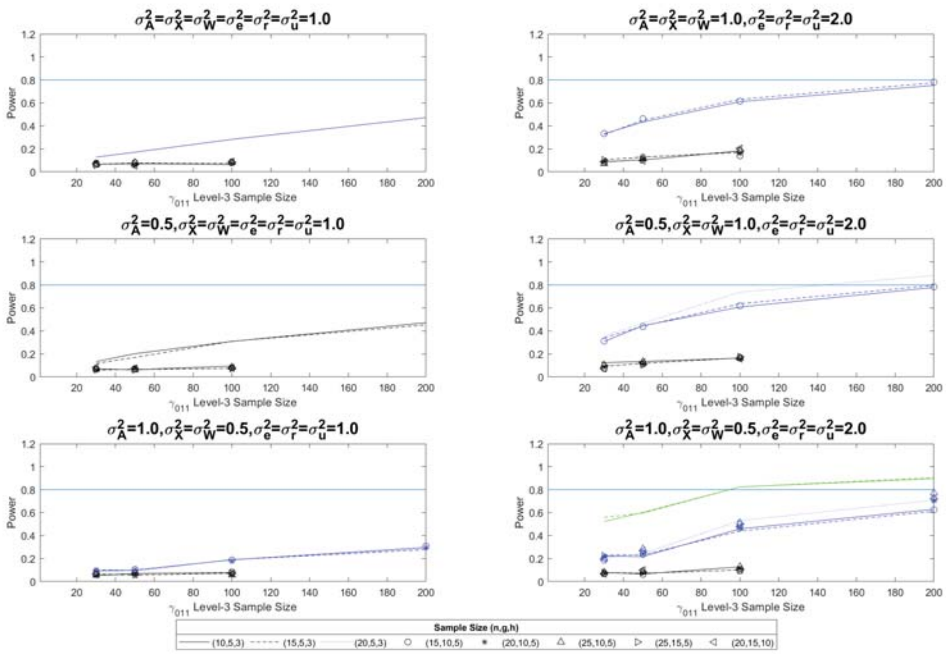

Figure 40. Level-3 γ_{011} re-sampled sample size power results for varying effect sizes (0.1 black, 0.3 blue, and 0.7 green) and scenarios with initial error variance $\sigma_e^2 = \sigma_r^2 = 1$ such that $\sigma_A^2 = \sigma_X^2 = \sigma_X^2 = 1.0$ (top), $\sigma_A^2 = 0.5$, $\sigma_X^2 = \sigma_X^2 = 1.0$ (middle), and $\sigma_A^2 = 1.0$, $\sigma_X^2 = \sigma_X^2 = 0.5$ (bottom).

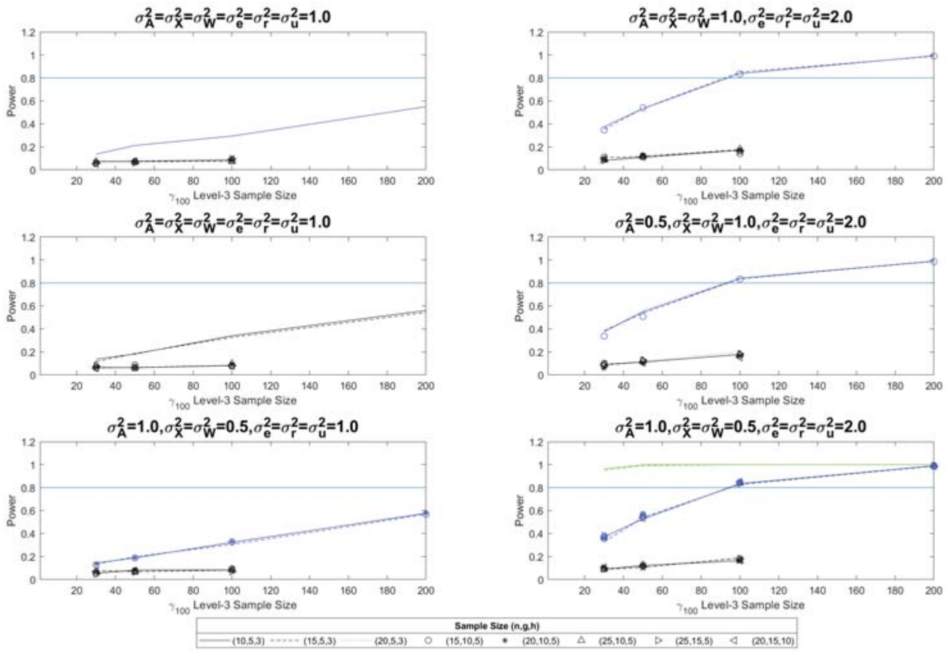

Figure 41. Level-3 γ_{100} re-sampled sample size power results for varying effect sizes (0.1 black, 0.3 blue, and 0.7 green) and scenarios with initial error variance $\sigma_e^2 = \sigma_r^2 = 1$ such that $\sigma_A^2 = \sigma_X^2 = \sigma_X^2 = 1.0$ (top), $\sigma_A^2 = 0.5$, $\sigma_X^2 = \sigma_X^2 = 1.0$ (middle), and $\sigma_A^2 = 1.0$, $\sigma_X^2 = \sigma_X^2 = 0.5$ (bottom).

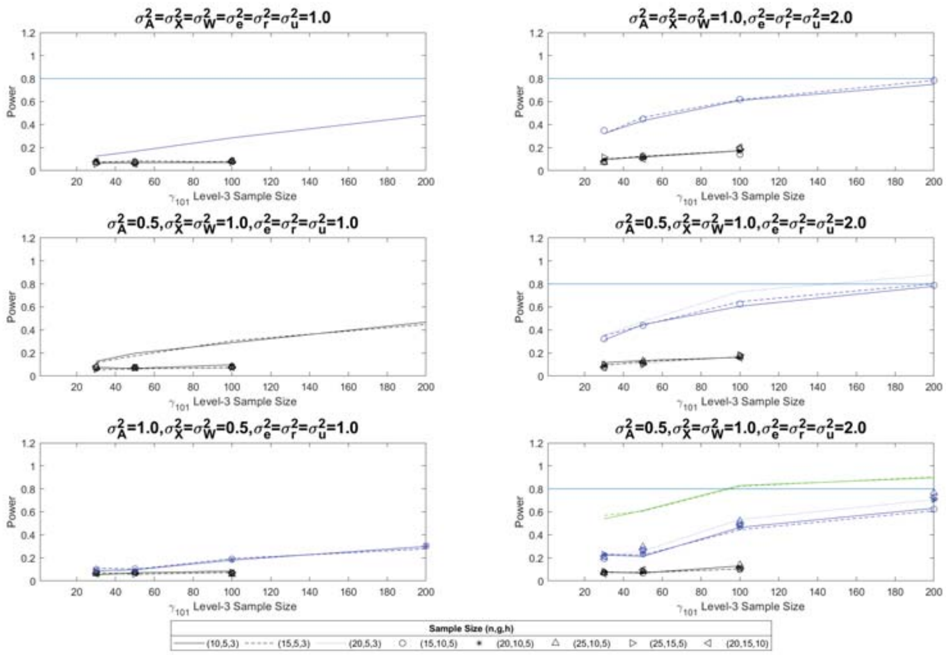

Figure 42. Level-3 γ_{101} re-sampled sample size power results for varying effect sizes (0.1 black, 0.3 blue, and 0.7 green) and scenarios with initial error variance $\sigma_e^2 = \sigma_r^2 = 1$ such that $\sigma_A^2 = \sigma_X^2 = \sigma_X^2 = 1.0$ (top), $\sigma_A^2 = 0.5$, $\sigma_X^2 = \sigma_X^2 = 1.0$ (middle), and $\sigma_A^2 = 1.0$, $\sigma_X^2 = \sigma_X^2 = 0.5$ (bottom).

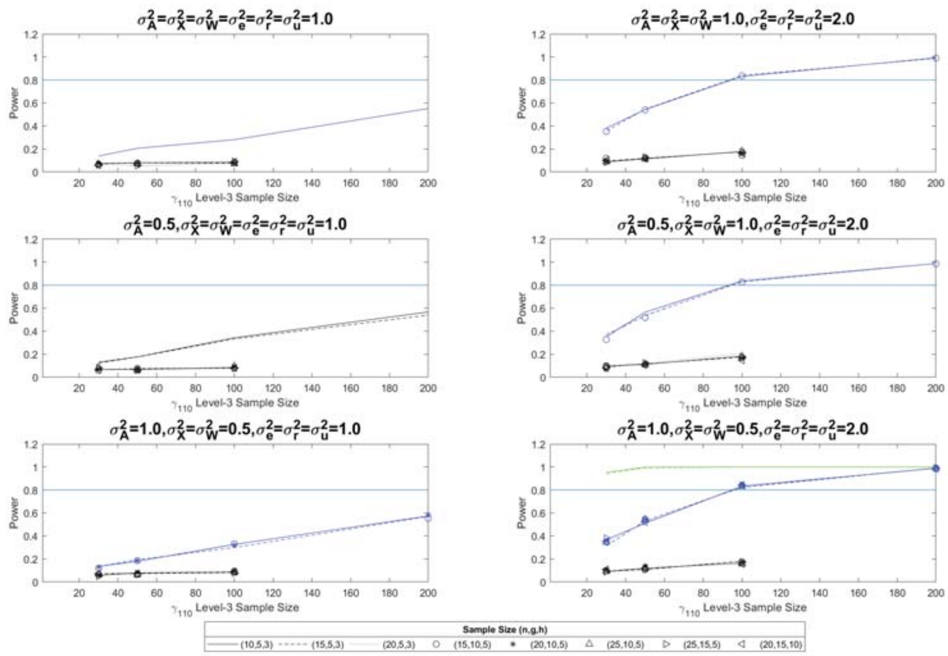

Figure 43. Level-3 γ_{110} re-sampled sample size power results for varying effect sizes (0.1 black, 0.3 blue, and 0.7 green) and scenarios with initial error variance $\sigma_e^2 = \sigma_r^2 = 1$ such that $\sigma_A^2 = \sigma_X^2 = \sigma_X^2 = 1.0$ (top), $\sigma_A^2 = 0.5$, $\sigma_X^2 = \sigma_X^2 = 1.0$ (middle), and $\sigma_A^2 = 1.0$, $\sigma_X^2 = \sigma_X^2 = 0.5$ (bottom).

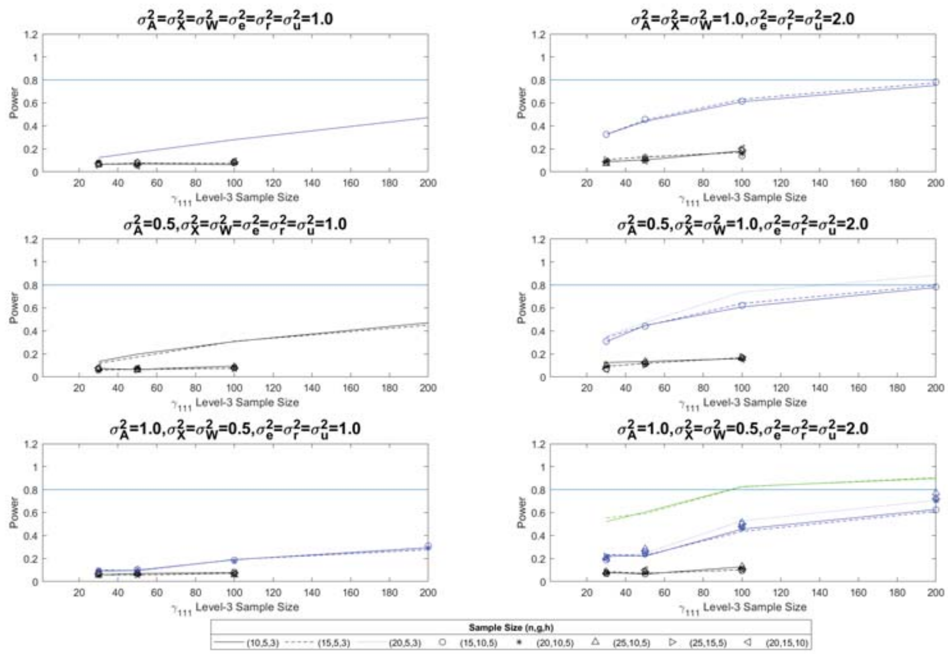

Figure 44. Level-3 γ_{111} re-sampled sample size power results for varying effect sizes (0.1 black, 0.3 blue, and 0.7 green) and scenarios with initial error variance $\sigma_e^2 = \sigma_r^2 = 1$ such that $\sigma_A^2 = \sigma_X^2 = \sigma_X^2 = 1.0$ (top), $\sigma_A^2 = 0.5$, $\sigma_X^2 = \sigma_X^2 = 1.0$ (middle), and $\sigma_A^2 = 1.0$, $\sigma_X^2 = \sigma_X^2 = 0.5$ (bottom).

Table 25. Average power values for Level-3 parameters based on the re-sampled sample sizes for conditions 1 - 75. Minimum power between 0.80 and 0.90 highlighted in light green and greater than 0.90 highlighted in dark green.

Table 26. Average power values for Level-3 parameters based on the re-sampled sample sizes for conditions 76 - 150. Minimum power between 0.80 and 0.90 highlighted in light green and greater than 0.90 highlighted in dark green.

Level-3 Parameter Power

Table 27. Average power values for Level-3 parameters based on the re-sampled sample sizes for conditions 151 - 236. Minimum power between 0.80 and 0.90 highlighted in light green and greater than 0.90 highlighted in dark green.

Level-3 Parameter Power

The accuracy of the Level-3 parameter estimates was calculated by the absolute relative bias (Tables 28 to 27 and Figures 45 to 51). Similar to Level-2, as effect size increases from 0.1 to 0.7, the absolute relative bias decreases for all predictor and error variance scenarios considered. For initial error variance $\sigma_e^2 = 1.0$, the absolute relative bias (Figures 45 to 51: left-hand side) was less than initial error variance $\sigma_e^2 = 2.0$ (Figures 45 to 51: right-hand side) and most noticeable for effect size 0.7 (Figures: 45 to 51: shown in green).

Though the Level-3 parameters achieved minimum sufficient power of 0.80 with fewer re-sampled samples at each level for initial error variance $\sigma_e^2 = 2.0$ and effect size 0.3 and 0.7, the associated parameters when re-sampled to larger sample sizes had larger absolute relative bias. Whereas, initial error variance $\sigma_e^2 = 1.0$ required more samples per level, the associated parameters when re-sampled to larger sample sizes had smaller absolute relative bias overall. The average absolute relative bias remains fairly consistent across re-sampled sample sizes (variations are due to averaging) and ranges from about 0.00 to 0.30.

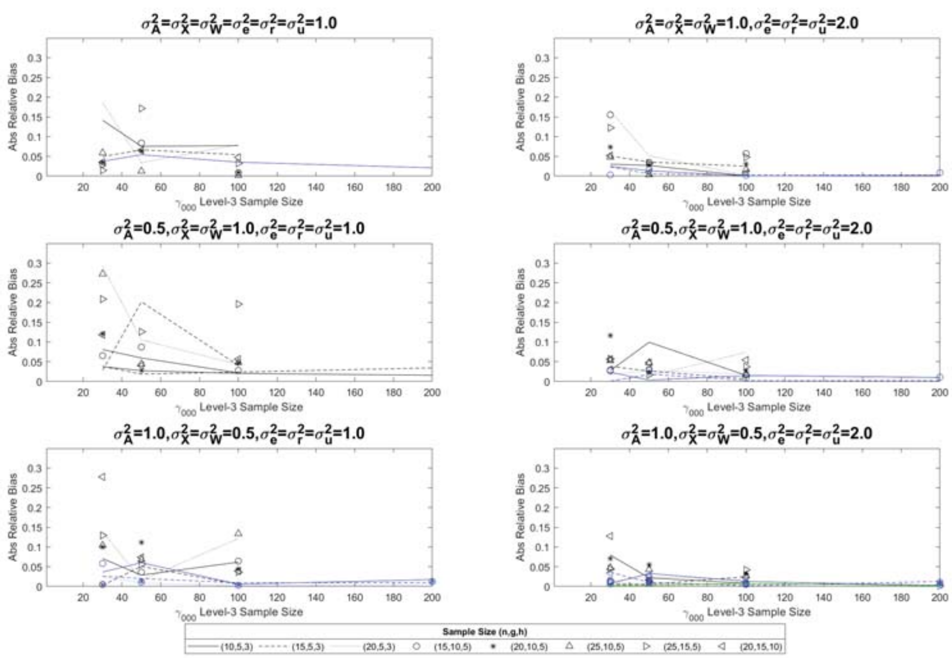

Figure 45. Level-3 γ_{000} re-sampled sample size absolute relative bias results for varying effect sizes (0.1 black, 0.3 blue, and 0.7 green) and scenarios $\sigma_A^2 = \sigma_X^2 = \sigma_W^2 = 1.0$ (top), $\sigma_A^2 = 0.5$,$\sigma_X^2 = \sigma_W^2 = 1.0$ (middle), and $\sigma_A^2 = 1.0$,$\sigma_X^2 = \sigma_W^2 = 0.5$ (bottom).

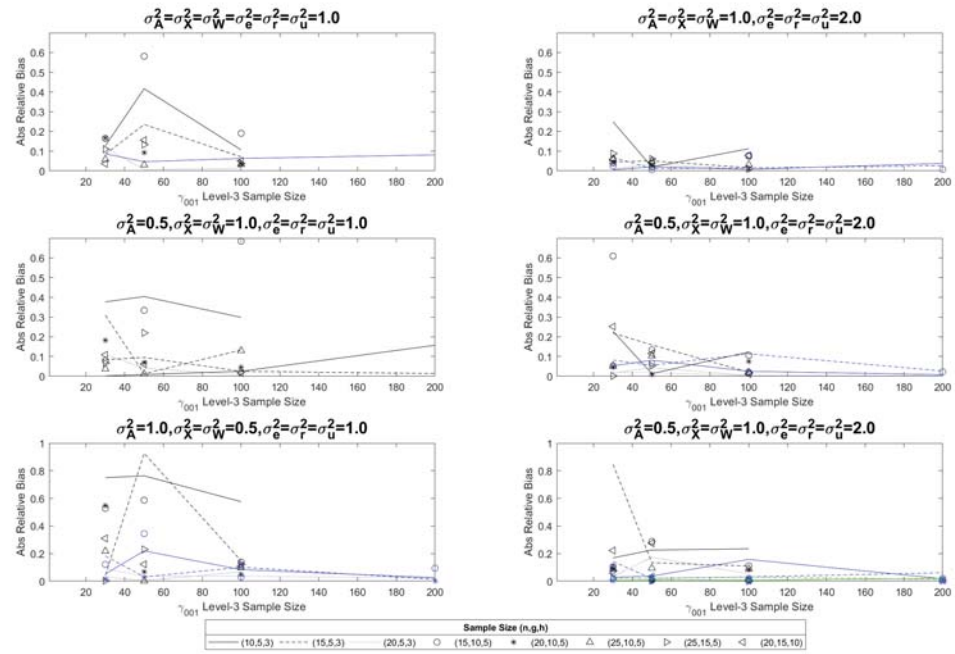

Figure 46. Level-3 γ_{001} re-sampled sample size absolute relative bias results for varying effect sizes (0.1 black, 0.3 blue, and 0.7 green) and scenarios $\sigma_A^2 = \sigma_X^2 = \sigma_W^2 = 1.0$ (top), $\sigma_A^2 = 0.5$,$\sigma_X^2 = \sigma_W^2 = 1.0$ (middle), and $\sigma_A^2 = 1.0$,$\sigma_X^2 = \sigma_W^2 = 0.5$ (bottom).

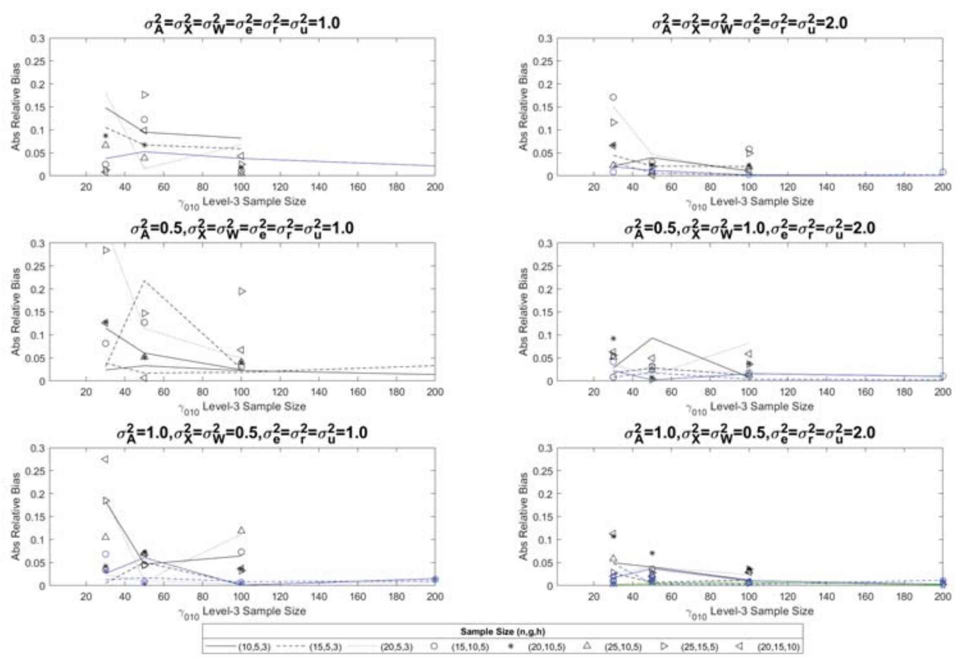

Figure 47. Level-3 γ_{010} re-sampled sample size absolute relative bias results for varying effect sizes (0.1 black, 0.3 blue, and 0.7 green) and scenarios $\sigma_A^2 = \sigma_X^2 = \sigma_W^2 = 1.0$ (top), $\sigma_A^2 = 0.5$,$\sigma_X^2 = \sigma_W^2 = 1.0$ (middle), and $\sigma_A^2 = 1.0$,$\sigma_X^2 = \sigma_W^2 = 0.5$ (bottom).

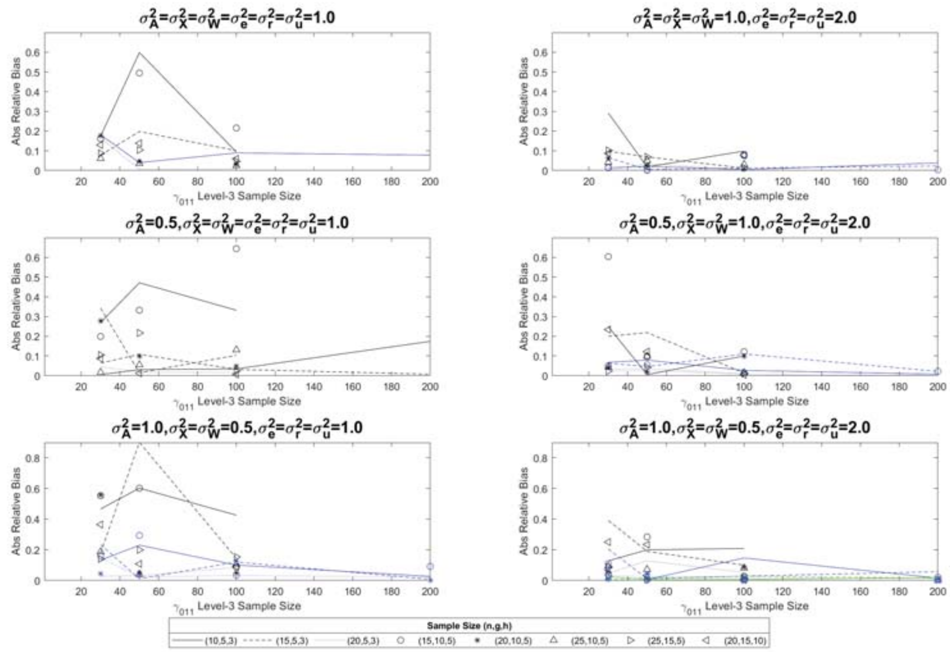

Figure 48. Level-3 γ_{011} re-sampled sample size absolute relative bias results for varying effect sizes (0.1 black, 0.3 blue, and 0.7 green) and scenarios $\sigma^2_A = \sigma^2_X = \sigma^2_W = 1.0$ (top), $\sigma^2_A = 0.5$,$\sigma^2_X = \sigma^2_W = 1.0$ (middle), and $\sigma^2_A = 1.0$,$\sigma^2_X = \sigma^2_W = 0.5$ (bottom).

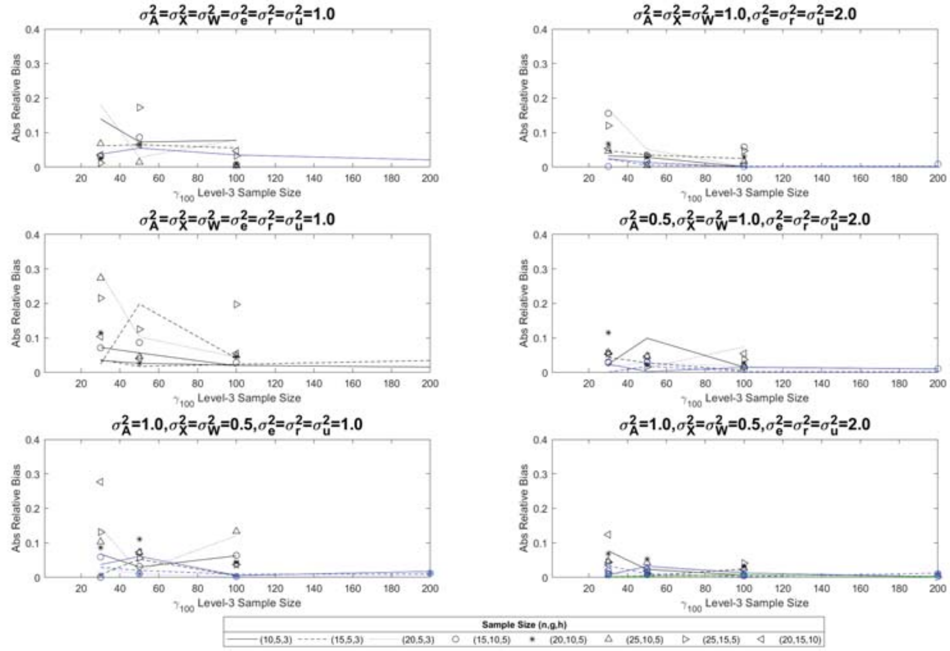

Figure 49. Level-3 γ_{100} re-sampled sample size absolute relative bias results for varying effect sizes (0.1 black, 0.3 blue, and 0.7 green) and scenarios $\sigma_A^2 = \sigma_X^2 = \sigma_W^2 = 1.0$ (top), $\sigma_A^2 = 0.5$,$\sigma_X^2 = \sigma_W^2 = 1.0$ (middle), and $\sigma_A^2 = 1.0$,$\sigma_X^2 = \sigma_W^2 = 0.5$ (bottom).

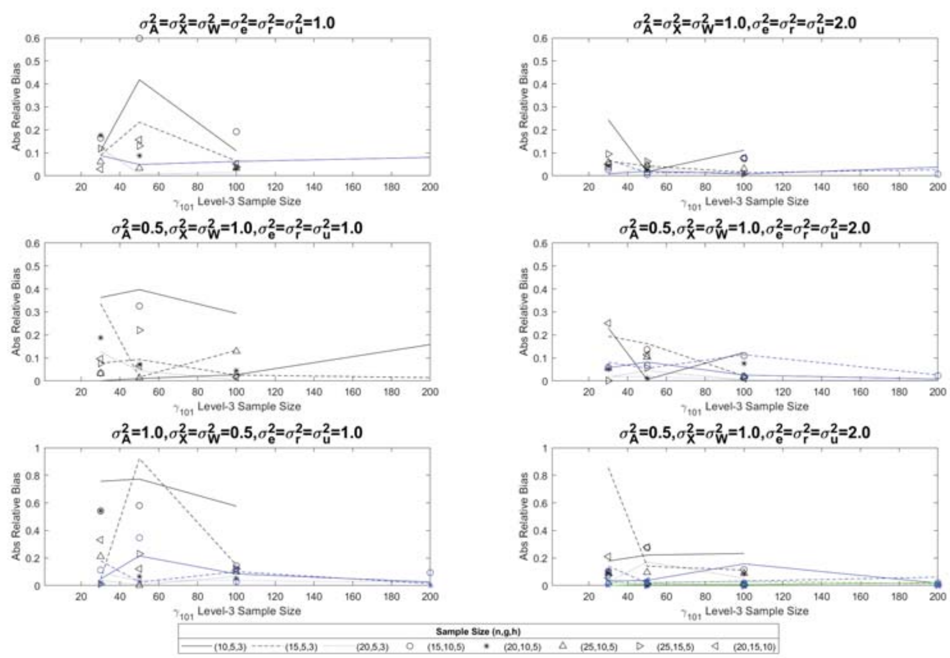

Figure 50. Level-3 γ_{101} re-sampled sample size absolute relative bias results for varying effect sizes (0.1 black, 0.3 blue, and 0.7 green) and scenarios $\sigma_A^2 = \sigma_X^2 = \sigma_W^2 = 1.0$ (top), $\sigma_A^2 = 0.5$,$\sigma_X^2 = \sigma_W^2 = 1.0$ (middle), and $\sigma_A^2 = 1.0$,$\sigma_X^2 = \sigma_W^2 = 0.5$ (bottom).

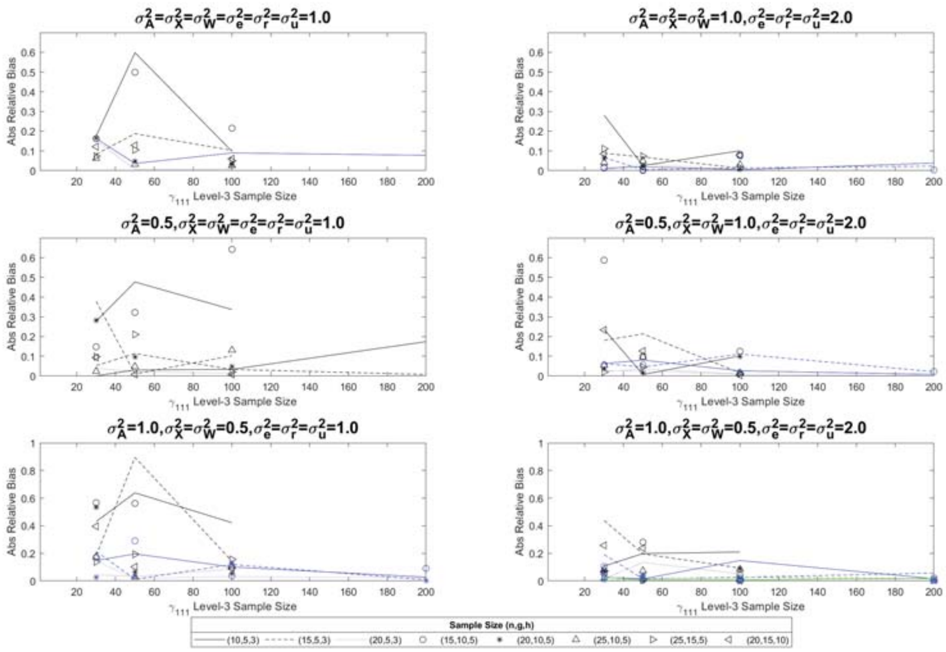

Figure 51. Level-3 γ_{111} re-sampled sample size absolute relative bias results for varying effect sizes (0.1 black, 0.3 blue, and 0.7 green) and scenarios $\sigma_A^2 = \sigma_X^2 = \sigma_W^2 = 1.0$ (top), $\sigma_A^2 = 0.5$,$\sigma_X^2 = \sigma_W^2 = 1.0$ (middle), and $\sigma_A^2 = 1.0$,$\sigma_X^2 = \sigma_W^2 = 0.5$ (bottom).

Table 28. Average absolute relative bias values for Level-3 parameters based on the re-sampled sample sizes for conditions 1 - 75.

Level-3 Parameter Absolute Relative Bias

In general, for a Level-3 HLM with small sample sizes in order to achieve sufficient power of 0.80 for different effect sizes this research found that:

- For effect size 0.7, Level-3 intercept parameters (γ_{000}, γ_{100}, γ_{010}, γ_{110}) with small sample sizes achieved minimum sufficient power of 0.80 when re-sampled between 50 and 100 sample sizes per each level with initial error variance $\sigma_e^2 = 1.0$, and less than 30 sample sizes per level with initial error variance $\sigma_e^2 = 2.0$.

- Level-3 slope parameters (γ_{001}, γ_{101}, γ_{011}, γ_{111}) with effect size 0.7 and small sample sizes came close to achieving minimum sufficient power of 0.80 when re-sampled to 200 sample sizes per each level with initial error variance $\sigma_e^2 = 1.0$, and did achieve minimum sufficient power when re-sampled to 100 sample sizes per each level with initial error variance $\sigma_e^2 = 2.0$. For both cases, the re-sampled sample size depended on the level predictor variances.

- The intercept and slope parameters with effect size 0.3 and small sample sizes, achieved minimum power of 0.80 when re-sampled to 200 sample sizes per each level with initial error variance $\sigma_e^2 = 2.0$.

- Both intercept and slope parameters with effect size 0.1 and initial error variance ($\sigma_e^2 = 1.0, 2.0$) did not achieve minimum sufficient power when re-sampled to 200 sample sizes per each level.

- As effect size increased from 0.1 to 0.7, the bias for all Level-3 parameters decreases for all predictor and error variances considered.

- The bias for initial error variance scenarios with $\sigma_e^2 = 1.0$ is less than those with $\sigma_e^2 = 2.0$.

- For effect sizes 0.3 and 0.7 as the considered re-sampled sample size increases, the parameter bias increases.

- The overall average relative bias ranged from 0.00 to 0.30.

Summary.

For operationally realistic small sample sizes, when the parameters of Level-2 and Level-3 HLMs did not achieve minimum sufficient power of 0.80 for specific scenarios based on level predictor variances, initial error variance, and effect size, the small sample sizes considered were re-sampled to larger samples per each level. Depending on the level predictor variances, in general, when re-sampled sample sizes were considered, for medium and high effect sizes (0.3 and 0.7) minimum sufficient power of 0.80 was achieved. Though as the re-sampled sample size increased per each level, not only did the computation time exponentially increase, but the absolute relative bias did as well.

The re-sampling procedure demonstrated in this research shows that due to limitations such as population size, cost, access to data (i.e., analysts), and changing environments, minimum sufficient power could still be achieved for multi-level models and average absolute relative bias estimated primarily depending on effect size. The re-sampled sample sizes per each level introduced and shown in this research is a simulation procedure that does not directly interfere with the work effort or performance of operational HLMs. Though due to software limitations and run times, larger re-sampling and higher levels were not achievable. Further, with this caution in mind, larger sample sizes could be explored. However, we caution that the user should consider the smallest sample size required for the re-sampling and that at some point re-sampling sample size requirements could be too large in order to return appropriate level of absolute relative bias. With advancements in the software capabilities and computing power this process can be applied to higher levels and larger re-sampled sample sizes with greater precision in comparison to results from Level-2 and Level-3 scaled comparably.

To assess human-machine system performance, this research investigated the operational multi-level model the Air Force Distributed Command Ground System (AF DCGS). The AF DCGS is a Level-4 HLM and the Level-3 and Level-4 details are in Chapter V. Through power calculations, this research shows the need and benefit of the re-sampling procedure introduced in this research for sample size criteria.

V. Research Objective 3: Notional Example of DCGS Operational Application

5.1 Level-3 and Level-4 Air Force Notional DCGS Example

To understand Level-3 and Level-4 HLM human-machine systems, we primarily focus on the notional example of the Air Force Distributed Command Ground System Full Motion Video (AF DCGS FMV) PED cell consisting of the following five analyst positions: Eyes On, Screener, Eyes Off, MSA and Geo. The roles for each of these analysts is outlined in Table 31. The DCGS PED cell is a team of analysts that is given a list of Essential Elements of Information (EEIs) from customers down range. The EEIs define information needed to be captured and recorded within PowerPoint slides for evaluation and decision making. The PowerPoint slides are products and the workflow of the products and their accuracy can be measured by product accuracy and duration, communication, human interface, subjective metrics, and physiological metrics, outlined in Figure 52.

Position	**Roles**
Eyes On	- Observes the full-motion video (FMV) feed and interprets activities in the world as spoken verbalizations
Screener	- Leads and manages PED team - Captures Eyes On Interpretations as text - Disseminates findings and products - Maintains mission situational awareness - Coordinates with Partners
Eyes Off	- Backup support for Eyes On - Support MSA as needed in product generation
MSA	- Generates products - Coordinates with DOF for analytical enrichments
Geo	- Monitors “global” view of FMV - Supports maintenance of mission situational awareness - Supports MSA as needed in product generation

Table 31. Possible DCGS analyst positions and roles.

To understand the workflow of the DCGS for this specific Level-3 and Level-4 HLM application, assume a customer requested a single PowerPoint slide to be a product. To

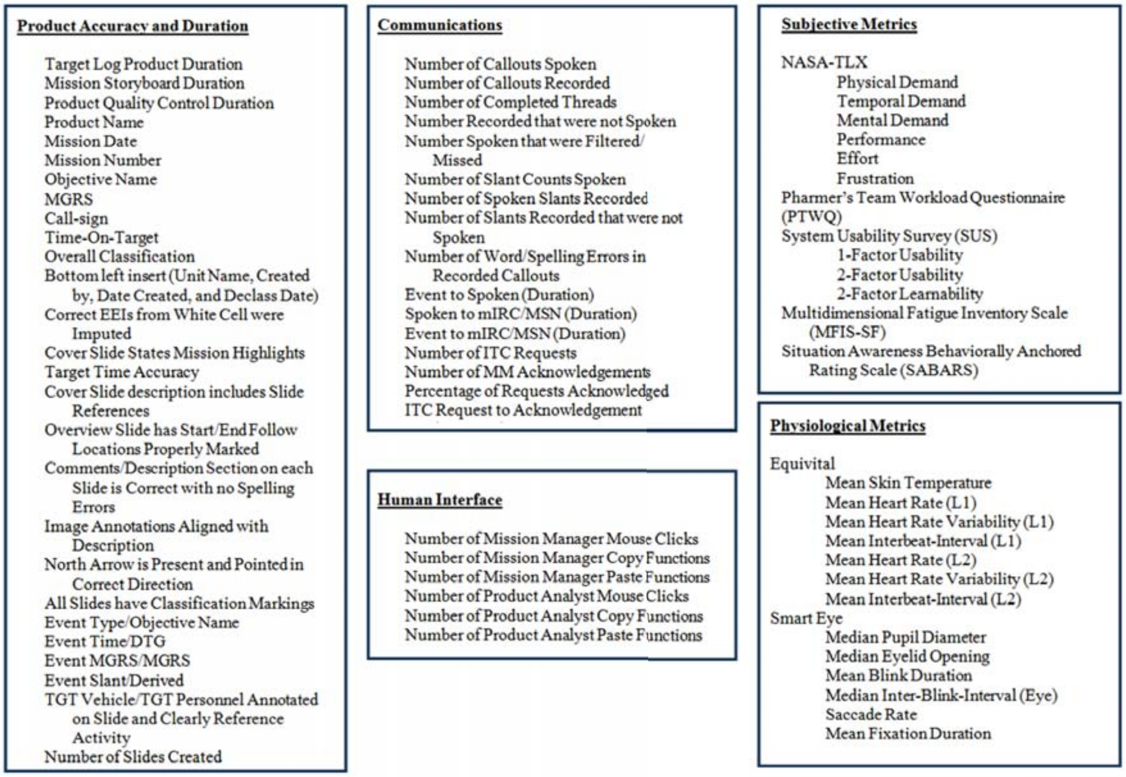

Figure 52. DGS-SOF PED cell metrics

determine the time in minutes to complete and submit a product to customer, (Y_{ijkl}), consider a Level-4 HLM model to be composed of the following levels: time to detect an EEI (Level-1: predictor variable A_{ijkl}), time to capture a callout in a chat (Level-2: predictor variable X_{ijkl}), time to create a product with request (Level-3: predictor variable X_{ijkl}), and time to quality control (QC) a product (Level-4: predictor variable Z_{ijkl}). The full Level-4 HLM for DCGS FMV is

$$
\begin{aligned}
Y_{ijkl} = {} & \delta_{0000} + \delta_{1000}A_{ijkl} + \delta_{0100}X_{ijkl} + \delta_{0010}W_{ijkl} + \delta_{0001}Z_{ijkl} + \delta_{1100}A_{ijkl}X_{ijkl} + \delta_{1010}A_{ijkl}W_{ijkl} \\
& + \delta_{1001}A_{ijkl}Z_{ijkl} + \delta_{0110}X_{ijkl}W_{ijkl} + \delta_{0101}X_{ijkl}Z_{ijkl} + \delta_{0011}W_{ijkl}Z_{ijkl} + \delta_{1110}A_{ijkl}X_{ijkl}W_{ijkl} \\
& + \delta_{1101}A_{ijkl}X_{ijkl}Z_{ijkl} + \delta_{1011}A_{ijkl}W_{ijkl}Z_{ijkl} + \delta_{0111}X_{ijkl}W_{ijkl}Z_{ijkl} + \delta_{1111}A_{ijkl}X_{ijkl}W_{ijkl}Z_{ijkl} \\
& + v_{111l}A_{ijkl}X_{ijkl}W_{ijkl} + v_{011l}X_{ijkl}W_{ijkl} + v_{101l}A_{ijkl}W_{ijkl} + v_{110l}A_{ijkl}X_{ijkl} \\
& + v_{001l}W_{ijkl} + v_{010l}X_{ijkl} + v_{100l}A_{ijkl} + v_{000l} \\
& + u_{11kl}A_{ijkl}X_{ijkl} + u_{00kl} + u_{01kl}X_{ijkl} + u_{10kl}A_{ijkl} + r_{1jkl}A_{ijkl} + r_{0jkl} + e_{ijkl}.
\end{aligned}
$$

In the absence of data, the predictor and error variance distributions of a hypothetical model are developed based on subject matter expert (SME) opinion. The distributions provided might not be normal, such as in this case, and normal transformations should be applied to use the findings of Research Objective 1 and 2 of this research to coincide with HLM assumptions. The final specific level distributions and transformations are outlined in Table 32. The current DCGS community consists of about 1,000 full-motion video (FMV) analysts and the associated sample sizes available at Level-1, Level-2, Level-3, and Level-4 are: 5 (for n), 8 (for g), 5 (for h), and 5 (for f), respectively [1, 2]. That is, 5 analysts per a PED (Level-2 individual), 8 PEDs per a unit (Level-2 team), 5 units per a site (Level-3 unit), and 5 sites total (Level-4 organization). Within the DCGS community, we assume the novice (less experienced) analyst models, PED cell, unit, and organization have more variability per level (e.g., error variance by level $\sigma_e^2, \sigma_r^2, \sigma_u^2, \sigma_v^2$) than the expert (more experienced) analyst models. This notional application compares both the novice and expert analyst models for both a Level-3 and Level-4 HLM.

Table 32. Notional example of DCGS application and associated distributions by level

Level	Predictor Variable	Level Representation in Time	Assumed Distribution	Transformed Distribution
1	A_{ijkl}	time to detect an EEI	$Gamma(1.0, 0.07)$	Box-Cox $\lambda = 0.04$ $N(8.82, 23.43)$
2	X_{ijkl}	time to capture a callout in a chat	$Uniform(1, 2)$	$N(0.0016, 0.9943)$
3	W_{ijkl}	time to create a product with request	$Gamma(3.0, 1.11)$	Box-Cox $\lambda = 1.44$ $N(-1.49, 0.0045)$
4	Z_{ijkl}	time to perform quality control of a product	N(10,18.06)	
	Y_{ijkl}	Total time to complete and submit a product to customer	$Gamma(3.0, 3.0)$	Box-Cox $\lambda = 1.022$ $N(0.025, 0.0064)$

The Level-1 predictor, A_{ijkl}, is the time in minutes to detect an EEI. The data follows a

gamma distribution such that the median is 0.083 minutes (Equation 34) and almost all the EEIs (0.999) are detected within 0.333 minutes (Equation 35). These properties are given by:

$$\int_0^{0.083} \frac{1}{\Gamma(\alpha)\beta^{\alpha}} x^{\alpha-1} e^{-x/\beta} dx = 0.50, \tag{34}$$

$$\int_0^{0.333} \frac{1}{\Gamma(\alpha)\beta^{\alpha}} x^{\alpha-1} e^{-x/\beta} dx = 0.999. \tag{35}$$

Solving for α and β, the approximated gamma distribution is $Gamma(1.0, 0.07)$, (Figure 53), such that:

$$\int_0^{0.083} \frac{1}{\Gamma(1)0.07^1} x^{1-1} e^{-x/0.07} dx = \int_0^{0.083} \frac{1}{0.07} e^{-x/0.07} dx = 0.511,$$

$$\int_0^{0.333} \frac{1}{\Gamma(1)0.07^1} x^{1-1} e^{-x/0.07} dx = \int_0^{0.333} \frac{1}{0.07} e^{-x/0.07} dx = 0.999.$$

To approximate a normal distribution, 10,000 $Gamma(1.0, 0.7)$ iterations were run and the Box-Cox transformation with $\lambda = 0.04$ was found such that:

$$Box - Cox_{Gamma(1.0,0.07)} = \frac{{y_{Gamma(1.0,0.07)}}^{0.04} - 1}{0.01867}. \tag{36}$$

Therefore, the transformed Level-1 predictor distribution is $A_{ijkl} \sim N(8.82, 23.43)$, as given in Table 32.

The Level-2 predictor, X_{ijkl}, takes 1 to 2 minutes to capture a callout in a chat. The data follows the uniform distribution $Uniform(1, 2)$ (Figure 54). By the Probability Integral Transformation, $P(X \leq x) = x, 0 < x < 1$ (Theorem 2.1.10 of [9]), when the transformation $V = X - 1$ is applied to $X_{ijkl} \sim Uniform(0, 1)$. This transformation is needed to generate the cumulative distribution function (CDF) of the underlying normal distribution.

This transformed Level-2 predictor distribution $V_{ijkl} \sim N(0.0016, 0.9943)$ (Figure 54).

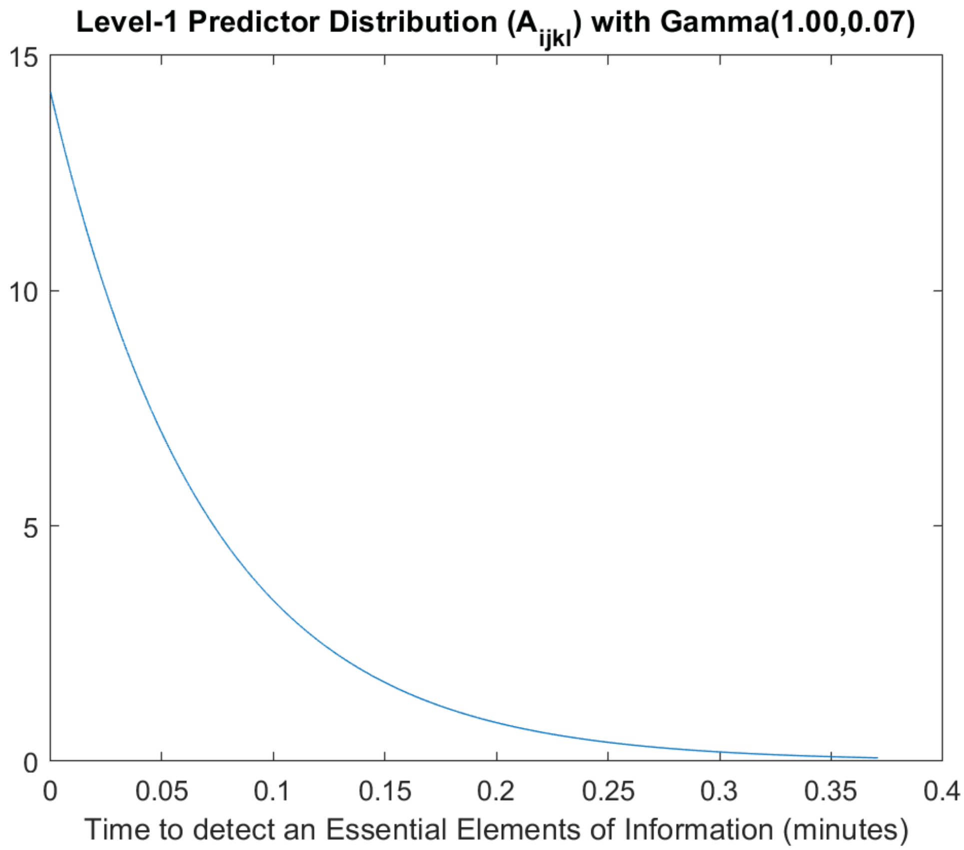

Figure 53. Level-1 predictor distribution (A$_{ijkl}$)

The Level-3 predictor, W_{ijkl}, is the time to create a product with customer request in minutes. The data follows a gamma distribution such that the median is 3 minutes (Equation 37) and almost all the EEIs (0.999) are detected within 10 minutes (Equation 38). These properties are given by:

$$\int_0^3 \frac{1}{\Gamma(\alpha)\beta^\alpha} x^{\alpha-1} e^{-x/\beta} dx = 0.50, \tag{37}$$

$$\int_0^{10} \frac{1}{\Gamma(\alpha)\beta^\alpha} x^{\alpha-1} e^{-x/\beta} dx = 0.999. \tag{38}$$

Solving for α and β, the approximated gamma distribution is $Gamma(3.0, 1.11)$, (Figure 55), such that:

$$\int_0^5 \frac{1}{\Gamma(3)1.11^3} x^{3-1} e^{-x/1.11} dx = \int_0^5 \frac{1}{(2)1.11^3} x^2 e^{-x/1.11} dx = 0.507,$$

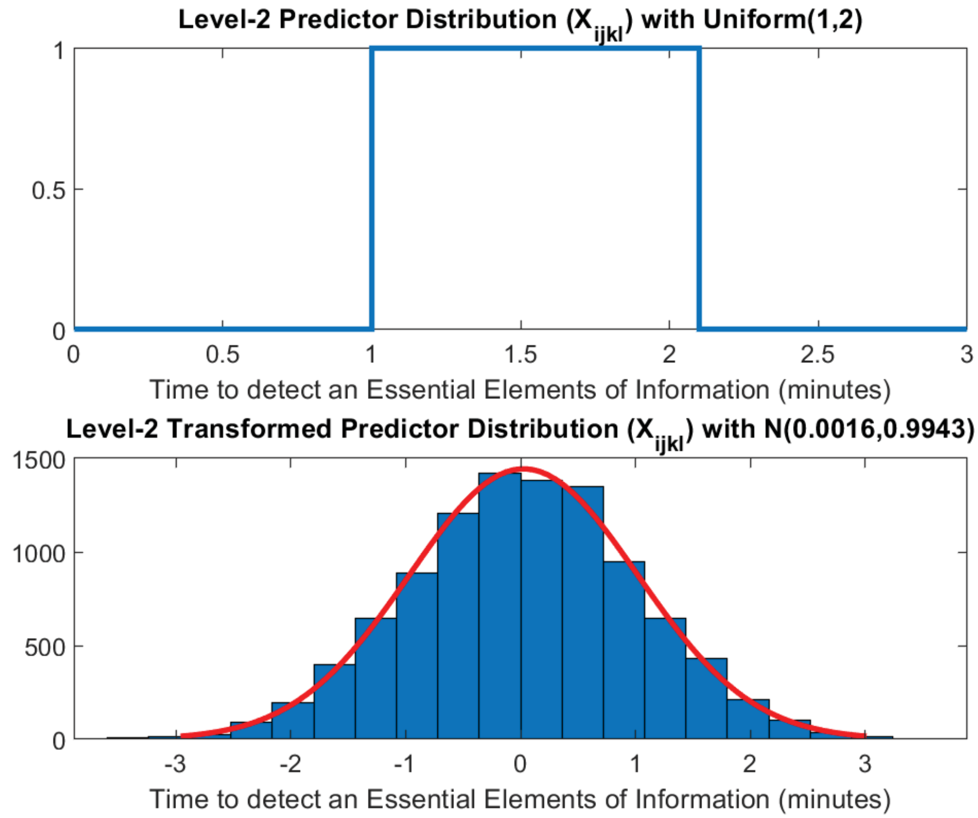

Figure 54. Level-2 predictor distribution ($\mathbf{X}_{ijkl}$)

$$\int_0^{20} \frac{1}{\Gamma(3)1.11^3} x^{3-1} e^{-x/1.11} dx = \int_0^{20} \frac{1}{(2)1.11^3} x^2 e^{-x/1.11} dx = 0.994.$$

To approximate a normal distribution, 10,000 $Gamma(3.0, 1.11)$ iterations were run and the Box-Cox transformation with $\lambda = 1.444$ was found (Figure 55) such that:

$$Box - Cox_{Gamma(3.0,1.11)} = \frac{y_{Gamma(3.0,1.11)}{}^{1.444} - 1}{0.61599}. \tag{39}$$

Therefore, the transformed Level-3 predictor distribution is $W_{ijkl} \sim N(-1.49, 0.0045)$, as given in Table 32.

The Level-4 predictor, Z_{ijkl}, is the time to submit and perform quality control of a product in minutes. The data follows a normal distribution $Z_{ijkl} \sim N(10, \sigma^2)$, (Figure 56),

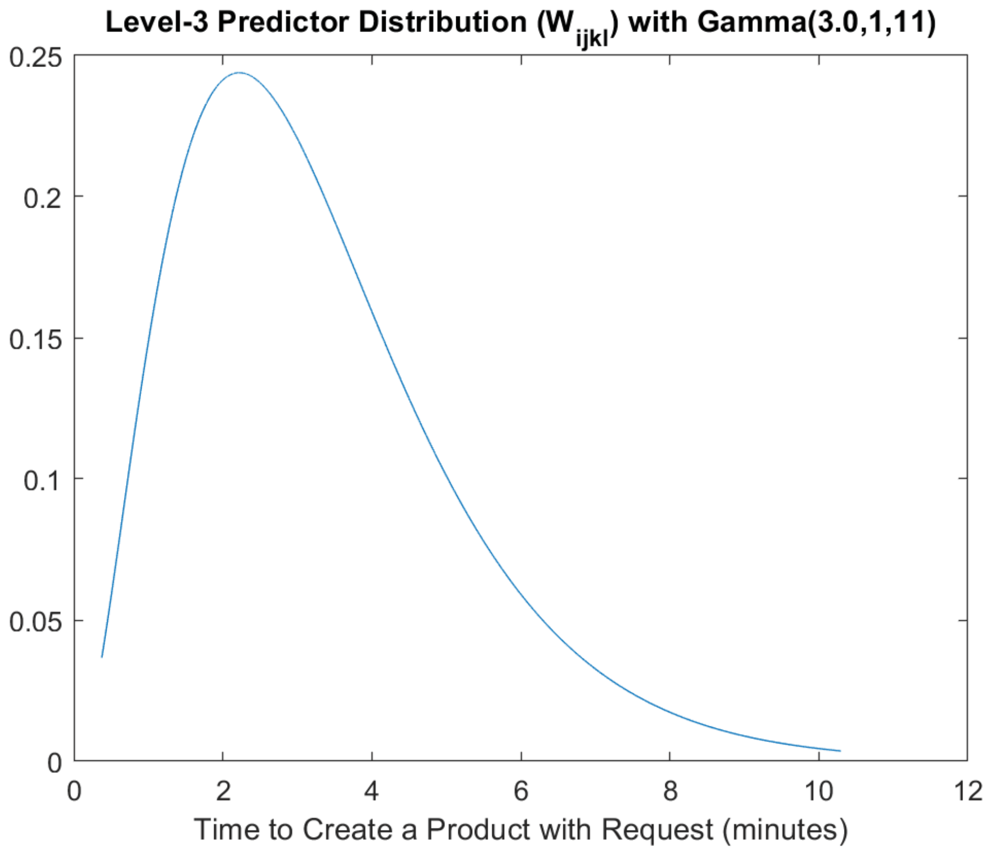

Figure 55. Level-3 predictor distribution ($\mathbf{W}_{ijkl}$)

such that the data within three standard deviations, 3σ, of the mean account for about 99.7% of all the time to perform quality control of the product. That is:

$$P(-3 \leq z \leq 3) = P(-3 \leq \frac{z-10}{\sigma} \leq 3) = 0.997$$

$$\implies P(-3\sigma \leq z - 10 \leq 3\sigma) = 0.997$$

$$\implies P(-3\sigma + 10 \leq z \leq 3\sigma + 10) = 0.997.$$

Since $Z_{ijkl} \sim N(10, \sigma^2)$, this implies

$$P(-3\sigma + 10 \leq z \leq 3\sigma + 10) = \int_{-3\sigma}^{3\sigma+10} \frac{1}{\sqrt{2\pi}} e^{-\frac{(z-10)^2}{2}} dx = 0.997 \tag{40}$$

and σ is approximately 4.25. Therefore, the Level-4 predictor distribution is

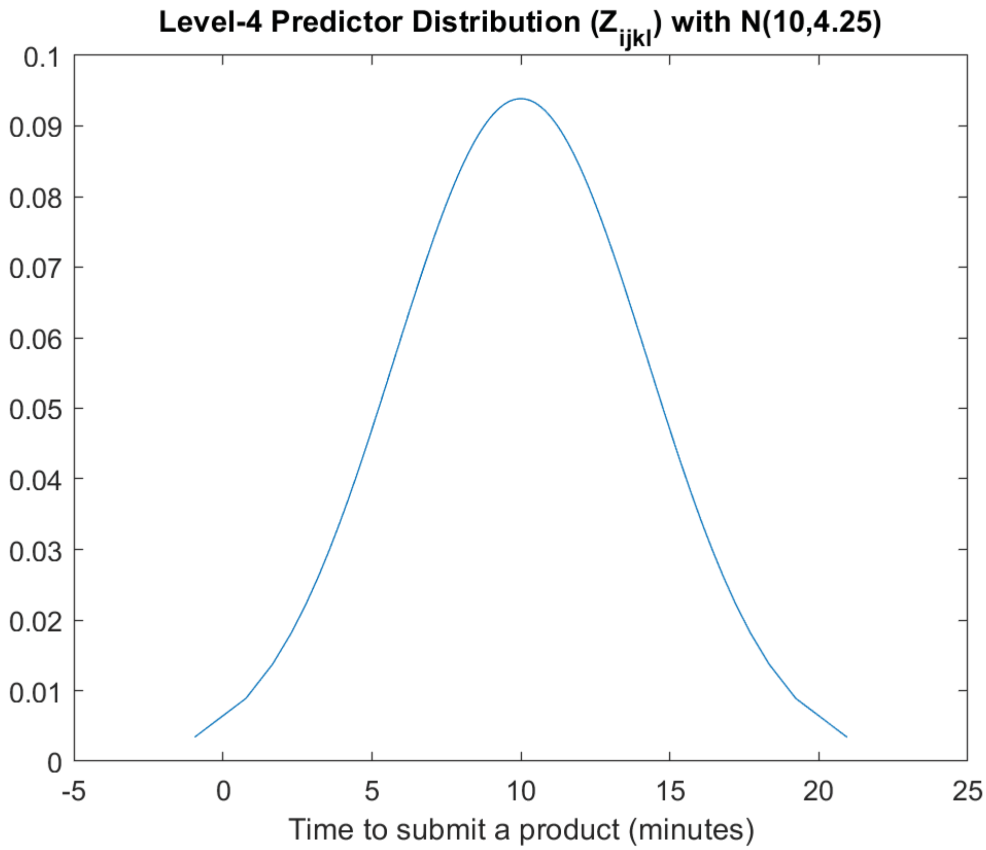

Figure 56. Level-4 predictor distribution ($\mathbf{Z}_{ijkl}$)

$Z_{ijkl} \sim N(10, 18.06)$, as given in Table 32.

The response, Y_{ijkl}, is the total time to complete and submit a product to a customer. The data follows a gamma distribution such that the median is 8 minutes (Equation 41) and total time is within 30 minutes (Equation 42). The following distributions, respectively, are:

$$\int_0^8 \frac{1}{\Gamma(\alpha)\beta^\alpha} x^{\alpha-1} e^{-x/\beta} dx = 0.50, \tag{41}$$

$$\int_0^{30} \frac{1}{\Gamma(\alpha)\beta^\alpha} x^{\alpha-1} e^{-x/\beta} dx = 0.999. \tag{42}$$

The approximated gamma distribution is $Gamma(3.0, 3.0)$, (Figure 57), such that:

$$\int_0^8 \frac{1}{\Gamma(3)3^3} x^{3-1} e^{-x/3} dx = \int_0^8 \frac{1}{54} x^2 e^{-x/3} dx = 0.498,$$

$$\int_0^{30} \frac{1}{\Gamma(3)3^3} x^{3-1} e^{-x/3} dx = int_0^{30} \frac{1}{54} x^2 e^{-x/3} dx = 0.997.$$

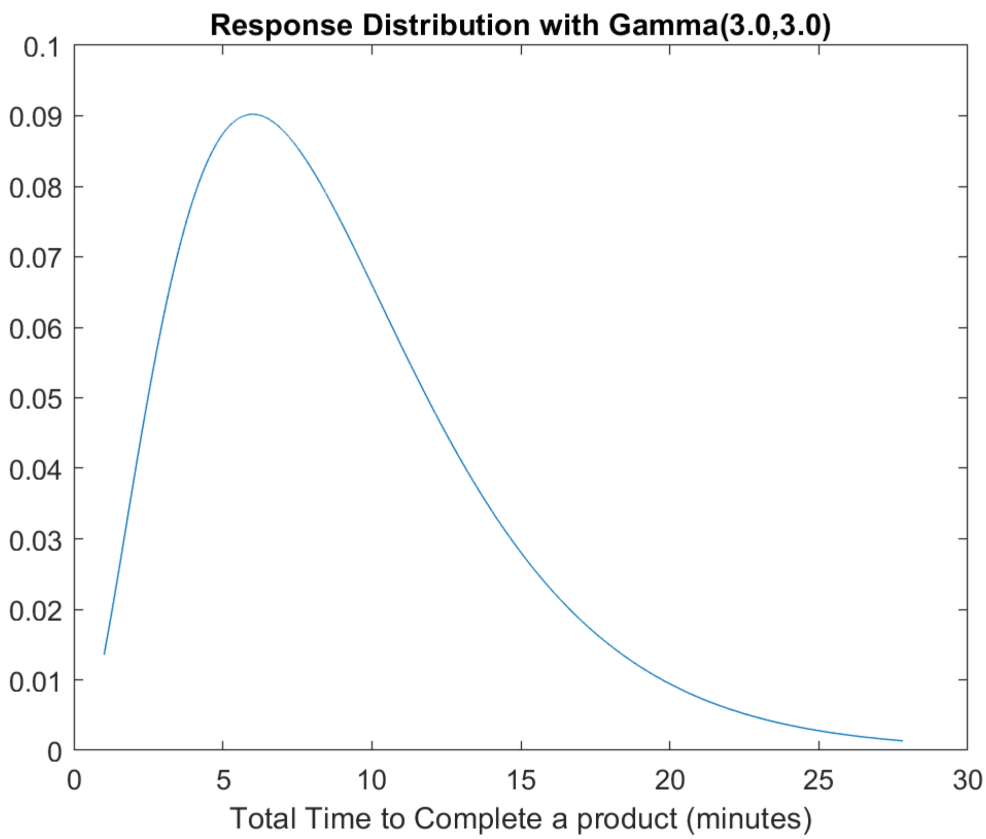

Figure 57. Response distribution ($\mathbf{Y}_{ijkl}$)

To approximate a normal distribution, 10,000 $Gamma(3.0, 3.0)$ iterations were run and the Box-Cox transformation with $\lambda = 1.022$ (Figure 57) was found such that:

$$Box - Cox_{Gamma(3.0,3.0)} = \frac{{y_{Gamma(3.0,3.0)}}^{1.022} - 1}{0.95856}. \tag{43}$$

Therefore, the transformed response distribution is $Y_{ijkl} \sim N(0.025, 0.0064)$, as given in Table 32.

The distributions (Equation 36, 39, 40), derived parameter standard errors (Equations

27, 30), and power equation (Equation 19) are used to determine the required sample sizes needed per level for a Level-3 and Level-4 DCGS HLM to achieve minimum power of at least 0.80 for both the expert and novice DCGS analysts. The minimum sample sizes per level are compared to the known population sample sizes and whether sample size extrapolation is necessary such as in Research Objective 2.

Level-3 Notional DCGS FMV HLM Example.

The Level-3 HLM DCGS FMV HLM is

$$\begin{aligned} Y_{ijk} &= \gamma_{000} + \gamma_{010}X_{ijk} + \gamma_{001}W_{ijk} + \gamma_{011}X_{ijk}W_{ijk} + \gamma_{100}A_{ijk} \\ &+ \gamma_{101}A_{ijk}W_{ijk} + \gamma_{110}A_{ijk}X_{ijk} + \gamma_{111}A_{ijk}X_{ijk}W_{ijk} + u_{11k}A_{ijk}X_{ijk} \\ &+ u_{00k} + u_{01k}X_{ijk} + u_{10k}A_{ijk} + r_{1jk}A_{ijk} + r_{0jk} + e_{ijk}. \end{aligned} \tag{44}$$

The power equation, $z_\pi \approx 1 - \Phi\left(\frac{\hat{\gamma}-\gamma}{s.e.(\hat{\gamma})} + z_{1-\alpha/2}\right)$, first introduced in Equation 19, of a Level-3 notional DCGS HLM example is derived from the estimated effect size, significance level, total sample size ($N = ngh$), and the parameter standard errors. Based on the current DCGS community, there at most $N = (5)(8)(5) = 200$ total samples available with which to build an HLM. In order to find the associated power for varying estimated effect sizes (0.1, 0.3, and 0.7), recall:

$$s.e.(\hat{\gamma}) = \begin{bmatrix} \sqrt{\frac{\sigma^2_{Level-3}}{N}} & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & \sqrt{\frac{\sigma^2_{Level-3}}{N\sigma^2_A}} & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & \sqrt{\frac{\sigma^2_{Level-3}}{N\sigma^2_X}} & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & \ddots & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & \sqrt{\frac{\sigma^2_{Level-3}}{N\sigma^2_A\sigma^2_W}} & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & \sqrt{\frac{\sigma^2_{Level-3}}{N\sigma^2_X\sigma^2_W}} & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & \sqrt{\frac{\sigma^2_{Level-3}}{N\sigma^2_A\sigma^2_W A}} \end{bmatrix},$$

which was first derived in Equation 27, and restated here. Power is derived based on the following conditions:

- Sample size $N = 200$;
- Assumed estimated effect sizes $\hat{\gamma} - \gamma = 0.1, 0.3, 0.7$;
- Derived predictor distributions by level (Equations 36, 39);
- Variance of $\mathbf{Y}$ equal to $\sigma^2_{Level-3} = \gamma^2_{010}\sigma^2_X + \gamma^2_{001}\sigma^2_W + \gamma^2_{011}\sigma^2_X\sigma^2_W + \gamma^2_{100}\sigma^2_A + \gamma^2_{101}\sigma^2_A\sigma^2_W + \gamma^2_{110}\sigma^2_A\sigma^2_X + \gamma^2_{111}\sigma^2_A\sigma^2_X\sigma^2_W + \sigma^2_u\sigma^2_A\sigma^2_X + \sigma^2_u + \sigma^2_u\sigma^2_X + \sigma^2_u\sigma^2_A + \sigma^2_r\sigma^2_A + \sigma^2_r + \sigma^2_e$;
- Level-3 HLM error variance by level for the expert analysts model ($\sigma^2_e = \sigma^2_r = \sigma^2_u = 1.0$) and novice analysts model ($\sigma^2_e = \sigma^2_r = \sigma^2_u = 2.0$).

Table 33. Level-3 AF DCGS FMV power table for estimated effect sizes 0.1, 0.3, 0.7 and sample size N = 200.

Level-3 DCGS FMV Power Table								
			Effect Size					
Parameter	**Association**		**Expert Analysts**			**Novice Analysts**		
γ_{ijk}	**Level Predictor Variable**	**Level Representation in Time (minutes)**	0.1	0.3	0.7	0.1	0.3	0.7
γ_{000}	Grand Intercept		0.04	0.07	0.17	0.03	0.05	0.11
γ_{001}	Level-3 W_{ijkl}	Create a product with request	0.68	**1.00**	**1.00**	0.41	**1.00**	**1.00**
γ_{010}	Level-2 X_{ijkl}	Capture a callout in chat	0.04	0.07	0.17	0.03	0.05	0.11
γ_{011}	Level2, Level-3 $X_{ijkl}W_{ijkl}$	Capture a callout in chat and create a product with request	0.68	**1.00**	**1.00**	0.41	**1.00**	**1.00**
γ_{100}	Level-1 A_{ijkl}	Detect an EEI	0.03	0.03	0.04	0.03	0.03	0.04
γ_{101}	Level-1,Level3 $A_{ijkl}\ W_{ijkl}$	Detect an EEI and create a product with request	0.07	0.31	**0.87**	0.05	0.18	0.64
γ_{110}	Level-1,Level-2 $A_{ijkl}X_{ijkl}$	Detect an EEI and capture a callout in chat	0.03	0.03	0.04	0.03	0.03	0.04
γ_{111}	Level-1,Level-2,Level-3 $A_{ijkl}X_{ijkl}W_{ijkl}$	Detect an EEI, capture a callout in chat, and create a product with request	0.07	0.32	**0.87**	0.05	0.18	0.64

Based on the notional DCGS Level-3 HLM analysts size, the parameters that achieved minimum power of at least 0.80 were associated with the Level-3 predictor (W_{ijkl}) time in minutes to create a customer requested (the associated parameters are: γ_{001}, γ_{011}, γ_{101}, and γ_{111}). The parameter, γ_{001}, to create a product with request (W_{ijkl}), and the parameter, γ_{011}, to capture a callout in chat and create a product with request ($X_{ijkl}W_{ijkl}$) achieved power of 1.00 for medium and large estimated effect sizes (0.3 and 0.7) for both the expert and novice analysts models. Whereas, the parameter, γ_{101}, to detect an EEI and create a product with request ($A_{ijkl}W_{ijkl}$), and the parameter, γ_{111}, to detect an EEI, capture a callout in chat, and create a product with request ($A_{ijkl}X_{ijkl}W_{ijkl}$) achieved power of 0.87 for large estimated effect size (0.7) for only the expert analysts model (Table 33 and Figure 58). Similar to the power results of Research Objective 2, small estimated effect sizes, such as 0.1, did not achieve minimum sufficient power of 0.80.

All other parameters not associated with the third level ($\gamma_{000}, \gamma_{010}, \gamma_{100}, \gamma_{110}, \gamma_{111}$) require more sample sizes than the population to achieve sufficient power of 0.80. This implies for the notional DCGS Level-3 HLM, re-sampling such as in Research Objective 2, is needed to achieve a minimum power of 0.80 for the specific parameters: the grand intercept, effects detecting an EEI, callouts in chat, and their interactions. Based on the findings of Research Objective 2, the current DCGS FMV community has enough sample sizes for extrapolation for the PED cells (Level-2) and units (Level-3) because the small sample size 10 individuals, 5 PED cells, and 3 units was extrapolated to 100 samples per level and the novice model achieved sufficient power for medium and large (0.3 and 0.7) estimated effect sizes. If 5 more analysts per PED could be obtained, then sufficient power of 0.80 can be achieved for the novice model. The samples per level for PED cells (Level-2) and units (Level-3) is larger than the small sample set by 3 and 2 sample sizes per level, respectively. If PED cells or units could be combined or grouped such that the analysts at Level-1 increased, then it is possible to achieve sufficient power for the novice model through re-sampling for all three levels of the Level-3 notional DCGS FMV HLM example.

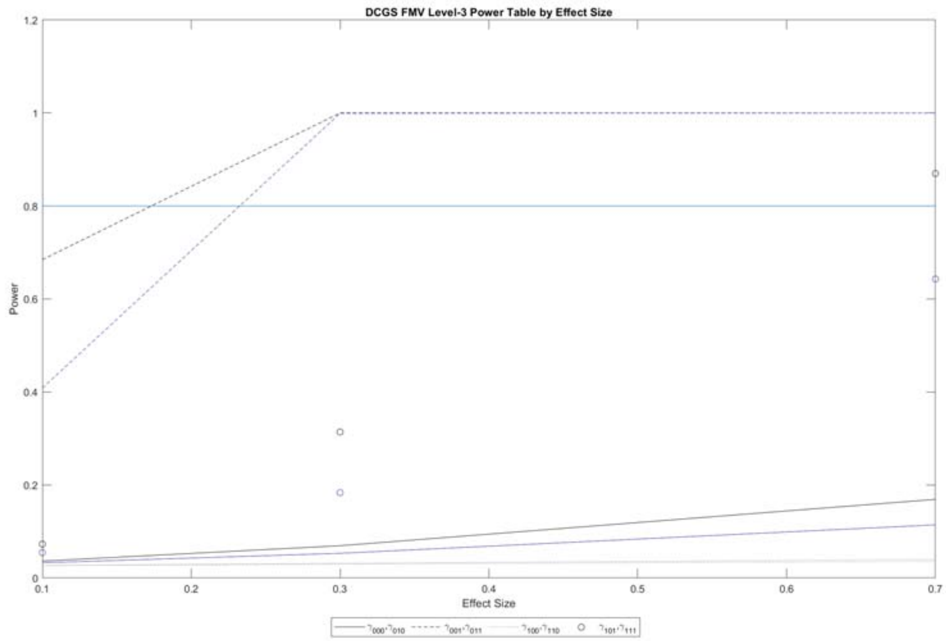

Figure 58. Level-3 AF DCGS FMV power plot for estimated effect sizes 0.1, 0.3, 0.7 and sample size N=200 for the expert (black) and novice (blue) analysts models.

Level-4 Notional DCGS FMV HLM Example.

Similar to Level-3 DCGS HLM, the power equation, $z_\pi \approx 1 - \Phi\left(\frac{\hat{\delta}-\delta}{s.e.(\hat{\delta})} + z_{1-\alpha/2}\right)$, first introduced in Equation 19, of a Level-4 notional DCGS HLM example is derived from the estimated effect size, significance level, total sample size ($N = nghf$), and the parameter standard errors. Based on the population, there is at most $N = (5)(8)(5)(5) = 1,000$ total samples with which to build an HLM. In order to find the associated power for varying estimated effect sizes (0.1, 0.3, and 0.7), recall:

$$s.e.(\hat{\delta}) = \begin{bmatrix} \sqrt{\frac{\sigma^2_{Level-4}}{N}} & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & \sqrt{\frac{\sigma^2_{Level-4}}{N\sigma^2_A}} & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & \sqrt{\frac{\sigma^2_{Level-4}}{N\sigma^2_X}} & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & \ddots & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & \sqrt{\frac{\sigma^2_{Level-4}}{N\sigma^2_A\sigma^2_W\sigma^2_Z}} & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & \sqrt{\frac{\sigma^2_{Level-4}}{N\sigma^2_X\sigma^2_W\sigma^2_Z}} & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & \sqrt{\frac{\sigma^2_{Level-4}}{N\sigma^2_A\sigma^2_X\sigma^2_W\sigma^2_Z}}. \end{bmatrix},$$

which was first derived in Equation 30, and restated here. Power is derived based on the following conditions:

- Sample size $N = 1,000$;
- Assumed estimated effect sizes $\hat{\delta} - \delta = 0.1,\ 0.3,\ 0.7$;
- Derived predictor distributions by level (Equations 36, 39, 40);
- Variance of $\mathbf{Y}$ equal to

  $\sigma^2_{Level-4} = \delta^2_{1000}\sigma^2_A + \delta^2_{0100}\sigma^2_X + \delta^2_{0010}\sigma^2_W + \delta^2_{0001}\sigma^2_Z + \delta^2_{1100}\sigma^2_A\sigma^2_X + \delta^2_{1010}\sigma^2_A\sigma^2_W + \delta^2_{1001}\sigma^2_A\sigma^2_Z + \delta^2_{0110}\sigma^2_X\sigma^2_W + \delta^2_{0101}\sigma^2_X\sigma^2_Z + \delta^2_{0011}\sigma^2_W\sigma^2_Z + \delta^2_{1110}\sigma^2_A\sigma^2_X\sigma^2_W + \delta^2_{1101}\sigma^2_A\sigma^2_X\sigma^2_Z + \delta^2_{1011}\sigma^2_A\sigma^2_W\sigma^2_Z + \delta^2_{0111}\sigma^2_X\sigma^2_W\sigma^2_Z + \delta^2_{1111}\sigma^2_A\sigma^2_X\sigma^2_W\sigma^2_Z + \sigma^2_r + \sigma^2_u + \sigma^2_v + \sigma^2_r\sigma^2_A + \sigma^2_u\sigma^2_A + \sigma^2_u\sigma^2_X + \sigma^2_u\sigma^2_A\sigma^2_X + \sigma^2_v\sigma^2_A + \sigma^2_v\sigma^2_X + \sigma^2_v\sigma^2_W + \sigma^2_v\sigma^2_A\sigma^2_X + \sigma^2_v\sigma^2_A\sigma^2_W + \sigma^2_v\sigma^2_X\sigma^2_W + \sigma^2_v\sigma^2_A\sigma^2_X\sigma^2_W + \sigma^2_e$;
- Level-4 HLM error variance by level for the expert analysts model ($\sigma^2_e = \sigma^2_r = \sigma^2_u = \sigma^2_v = 1.0$) and the novice analysts model ($\sigma^2_e = \sigma^2_r = \sigma^2_u = \sigma^2_v = 2.0$).

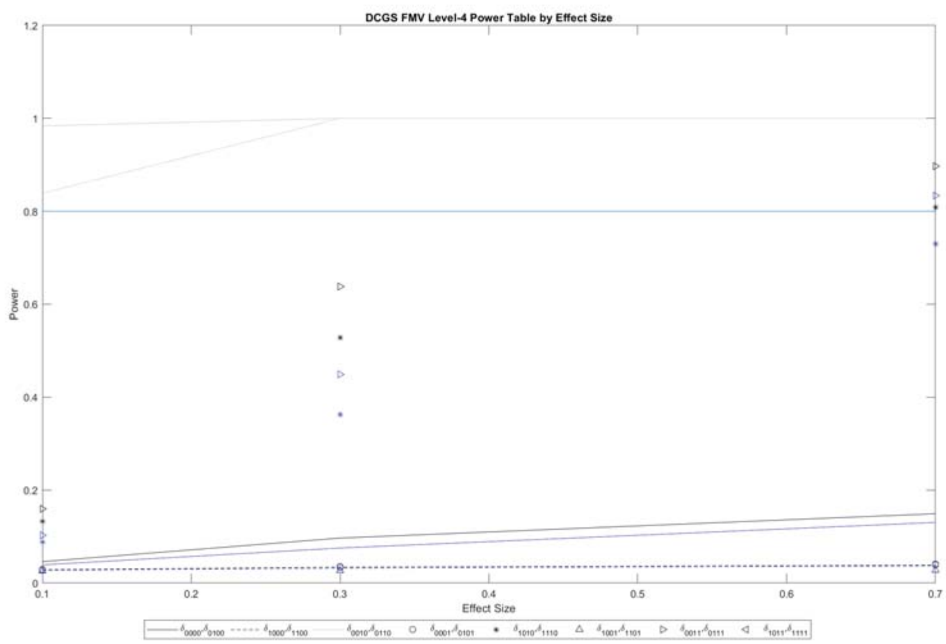

Figure 59. Level-4 AF DCGS FMV power plot for estimated effect sizes 0.1, 0.3, 0.7 and sample size N=1,000 for the expert (black) and novice (blue) analysts models.

Similar to Level-3, based on the current DCGS Level-4 HLM community size, the parameters that achieved minimum sufficient power of at least 0.80 were associated with Level-3 predictor, W_{ijkl}, time in minutes to create a customer requested product (the associated parameters are: δ_{0010}, δ_{1010}, δ_{0110}, δ_{0110}, δ_{0011}, δ_{1110}, and δ_{0111}). The parameter, δ_{0010}, to create a product with request (W_{ijkl}), and the parameter, δ_{0110}, to capture a callout in a chat and create a product with request ($X_{ijkl}W_{ijkl}$) achieved sufficient power greater than 0.80 for low, medium, and high estimated effect sizes (0.1, 0.3, 0.7) for both the expert and novice analysts models (Table 34 and Figure 59). The parameter, δ_{1010}, to detect an EEI and create a product with request ($A_{ijkl}W_{ijkl}$), and the parameter, δ_{1110}, to detect an EEI, capture a callout in a chat, and create a product with request ($A_{ijkl}X_{ijkl}W_{ijkl}$) achieved power of 0.81 for large estimated effect size (0.7) for only the expert analysts model and the parameter, δ_{0011}, to create a product with request and perform quality control of a product ($W_{ijkl}Z_{ijkl}$), and the parameter, δ_{0111}, to capture a callout in chat, create a product with requests, and perform quality control of a product ($X_{ijkl}W_{ijkl}Z_{ijkl}$) achieved power greater than 0.80 for large estimated effect size for both the expert and novice analysts models.

All other parameters, not associated with the third level (δ_{0000}, δ_{0100}, δ_{0001}, δ_{1100}, δ_{1001}, δ_{0101}, δ_{1101}, δ_{1011}, δ_{1111}), except δ_{1111}, required more sample sizes than the current sample size to achieve sufficient power of 0.80. This implies for the notional DCGS Level-4 HLM re-sampling is needed to achieve a minimum power of 0.80 for the specific parameters: the grand mean, capture a callout in chat, perform quality control of a product, and their interactions.

Summary.

The current DCGS FMV community consists of 1,000 analysts. Based on the current number of analysts and transformed distributions, in general, for medium and large estimated effect sizes, parameters associated with the Level-3 predictor, W_{ijkl} had power of at least 0.80. If these specific parameters, for both notional DCGS FMV Level-3 and

Level-4 HLMs, were of interest, then there is sufficient sample available based the current number analysts.

For the Level-3 and Level-4 HLM parameters that did not achieve a minimum power of at least 0.80, re-sampling to larger sample sizes at each level could be applied to achieve minimum sufficient power, because the sample sizes required are larger than the current DCGS FMV community. This application showed through simulation, that based on SME information, multi-level sample size recommendations could be provided to an operational customer for parameters associated with level predictors of interest.

VI. Discussion

The complex interrelated variability of the Level-4 HLM exists in many operational setting including the small population of the Air Force Distributed Common Ground System Full Motion Video (AF DCGS FMV) community. This nested data structure of 1,000 analysts can be represented by a Level-4 Hierarchical Linear Model (HLM). The data requirements and collection process of multi-level models, such as the DCGS FMV human-machine system, can be understood through the development of sample size requirements and small sample size re-sampling to larger sample sizes per each level when parameter estimation does not meet sufficient minimum power for statistical testing.

The parameter estimates of the Level-2, Level-3, and Level-4 HLMs are based on the associated parameter standard errors derived in this research and an assumption of independence between levels. The sample size criteria for sufficient statistical power are based on a variety of realistic operational scenarios for Level-2, Level-3 and Level-4 HLMs. The scenarios are defined such that the Level-1 predictor variability is greater than or equal to the variability of the groups, units, and organizations. The initial error values were chosen similar to existing Level-2 literature such that when the intraclass correlation coefficients were calculated, the values were generally moderate and largest at the lowest level. Small, medium, and large estimated effect sizes were considered for comparison to previous literature and for sample size recommendations.

Sample size recommendations for Level-2 HLMs parameter estimation previously existed, but recommendations have not been provided or extended to Level-3 and Level-4 HLMs. One of the most common Level-2 sample size recommendations is the general rule of thumb, 30 sample sizes per Level-1 and Level-2 to achieve minimum sufficient statistical power. This research found that for a Level-2 HLM, minimum sufficient power was not met when using only 30 samples sizes per level for small estimated effect size (0.1), but for larger estimated effect sizes (0.3 and 0.7), 30 sample sizes per level was more than sufficient and almost doubled what was needed to achieve sufficient power. This work

applied the general rule of thumb to the Level-3 and Level-4 HLMs variance scenarios considered, and found that 30 sample sizes per level was also more than sufficient.

In addition to sample size recommendations when compared to the general rule of thumb, this research compared variance values for varying level predictor and level error terms for Level-2, Level-3, and Level-4 HLMs. For all HLMs considered, this research found that as the estimated effect size increased, the number of sample sizes required to achieve minimum power per level decreased. That is, the stronger the strength (estimated effect size) between the parameter and system performance (response), the fewer sample sizes needed to achieve adequate power.

When the assumed error variance doubled for each level, the required sample sizes to achieve minimum statistical power increased. In other words, if HLMs of novice analyst models versus the expert analyst models were assessed, and the novice analyst models had double the variability of the expert analyst models, then the number of sample sizes required to achieve minimum statistical power in modeling would be more for the novice analyst models for all predictor and error variance scenarios considered.

Also, if the predictor variance at Level-1 is less than the higher levels (Level-2, Level-3, and Level-4), then the sample sizes per level required depends on the initial error variability and parameter of interest. This implies that the variability of the individual level (analyst) tasking was influential and affected the overall performance of the system with regards to sample sizes needed. Whereas, if the predictor variance at the higher levels decreased, the conclusions were more consistent and the sample sizes required per level generally increased for all predictors, but the pure intercepts. These samples size requirements assumed Independence between levels.Sample size criteria may differ when dependence is included.

Using the power results and sample size requirements derived for Research Objective 1, operationally realistic small sample size combinations were considered for re-sampling in order to meet sample size requirements. The small sample combinations considered reflect achievable sample sizes for each level based on small population sizes, cost, and limited

access to operational environments. For the specific predictor and error variance scenarios assumed, when the parameters of Level-2 and Level-3 HLMs did not achieve minimum sufficient statistical power for the small sample sizes considered, the small sample sizes were re-sampled to larger samples per each level of the HLM. For both Level-2 and Level-3 HLMs, in general, when small sample sizes were re-sampled to larger sample sizes, minimum sufficient statistical power was achieved for medium and high estimated effect sizes (0.3 and 0.7). Though as the re-sampled sample size increased per each level, not only did the average absolute relative bias of the parameter estimates increase, but the computation time exponentially increased as well. The re-sampling procedure introduced in this research is not limited to Level-3 HLMs and can be applied to higher levels.

To understand human and machine workloads of a system, this research can be applied to real-world multi-level applications if the predictor and error distributions are known estimates or have been observed by SMEs. For example, in Research Objective 3, the notional example of the AF DCGS FMV community distributions were computed based on SME observations and analyst products for both the novice and expert analyst models. For this specific example, to assess human-machine system performance and achieve minimum statistical power, the necessary sample sizes required per level for almost all parameters exceeded the population. For instance, power could not be achieved for the Level-3 HLM DCGS FMV analysis because for equal sample sizes per level, a minimum of 6 samples per level were required, for a total of $6 \times 6 \times 6 = 216$ observations. However, the population consists of 5 analysts per PED cell, 8 PED cells per unit, and 5 units, which means the number of analysts and units required for assessment is greater than the population allows and therefore could not be obtained. The analysis and sample size requirements should focused on the model parameters of interest. For instance, if the group and unit variables are of importance only, then power should be assessed for these levels. If these specific parameters of interest do not have enough statistical sufficient power, then the re-sampling procedure developed within this research could be applied. Determining the level parameters of interest could decrease the number of sample sizes per

level required and the number of re-samples needed to achieve statistical sufficient power.

If the Level-3 DCGS FMV sub-sample sizes per level were determined and the re-sampling procedure applied, sufficient statistical power could be achieved. Prior to this research, only subjective recommendations could be made to a customer, whereas now, a more in-depth simulation could be proposed that requires only limited resources, analysts' time, and could be done in a non-invasive manner.

As stated, the derived sample size equations can be generalized to any level of an HLM. In addition to obtaining the recommended sample sizes through experimentation and applying the re-sampling procedure to the DCGS FMV Level-3 HLM, future work would be to develop more robust software that could handle larger multi-level models and the re-sampling procedure (i.e., the DCGS FMV Level-4 HLM). In addition, this research considered HLMs with one predictor at each level and no predictor interactions at each level (only between levels). Though this research assumed that in each level, predictor effects are additive and therefore may be represented through one predictor variable at each level, this research could be extended to include additional predictor interactions within levels.

Finally, assessment of human-machine system performance is of most importance to the Air Force and the need for autonomous systems is growing. Due to rising operational costs, changing missions, small populations, complex environments, and absence of necessary data, the need for HLM assessments through simulations are crucial. Prior sample size recommendations and small sample size re-sampling are a step towards advancing the Air Force's capabilities and mission understanding for human-machine based systems.

VII. Appendix

Appendix A. Estimation of Maximum Likelihood (ML) Model.

The simple linear model can be rewritten as $\mathbf{Y_{Nx1}} = \mathbf{M_{Nxp}}\mu_{\mathbf{px1}} + \varepsilon_{\mathbf{Nx1}}$. Where N is the total sample size, p denotes the number of coefficients in the model, and $\varepsilon \sim N(0, \Sigma)$ such that $\Sigma = \sigma^2_{level} I$.

Likelihood.

The likelihood function, denoted L, of μ and Σ is

$$L = L(\mu, \mathbf{\Sigma}|\mathbf{y}) = \frac{exp\left[-\frac{1}{2}(\mathbf{y} - \mathbf{M}\mu)'\mathbf{\Sigma}^{-1}(\mathbf{y} - \mathbf{M}\mu)\right]}{(2\pi\mathbf{\Sigma})^{\frac{1}{2}N}}$$

By maximizing L, the maximum likelihood estimates of μ and Σ ($\hat{\mu}$ and $\hat{\Sigma}$, respectively) can be obtained. Note, that these estimates are more easily found using the log-likelihood where:

$$l = logL = -\frac{1}{2}Nlog(2\pi) - \frac{1}{2}Nlog|\mathbf{\Sigma}| - \frac{1}{2}(\mathbf{y} - \mathbf{M}\mu)'\mathbf{\Sigma}^{-1}(\mathbf{y} - \mathbf{M}\mu).$$

Since $tr[\mathbf{ABC}] = tr[\mathbf{CAB}] = tr[\mathbf{BCA}]$, this implies

$$\begin{aligned}
l &= -\frac{1}{2}Nlog(2\pi) - \frac{1}{2}Nlog|\mathbf{\Sigma}| - \frac{1}{2}(\mathbf{y} - \mathbf{M}\mu)'\mathbf{\Sigma}^{-1}(\mathbf{y} - \mathbf{M}\mu) \\
&= -\frac{1}{2}Nlog(2\pi) + \frac{1}{2}Nlog|\mathbf{\Sigma}^{-1}| - \frac{1}{2}(\mathbf{y} - \mathbf{M}\mu)'\mathbf{\Sigma}^{-1}(\mathbf{y} - \mathbf{M}\mu) \\
&\propto -\frac{1}{2}Nlog(2\pi) + \frac{1}{2}Nlog|\mathbf{\Sigma}^{-1}| - \frac{1}{2}tr[(\mathbf{y} - \mathbf{M}\mu)'\mathbf{\Sigma}^{-1}(\mathbf{y} - \mathbf{M}\mu)] \\
&= -\frac{1}{2}Nlog(2\pi) + \frac{1}{2}Nlog|\mathbf{\Sigma}^{-1}| - \frac{1}{2}tr[\mathbf{\Sigma}^{-1}(\mathbf{y} - \mathbf{M}\mu)(\mathbf{y} - \mathbf{M}\mu)']
\end{aligned}$$

ML Equations and Their Solutions.

To verify that the function l has a local maximum at $(\hat{\mu}, \hat{\Sigma})$, the following three conditions must be satisfied:

1. Possible candidates for the ML estimates are found by setting the first-order partial derivatives to 0 and replacing μ and Σ by the estimators $\hat{\mu}$ and $\hat{\Sigma}$, respectively. Since $\frac{\partial}{\partial \mathbf{A}}\mathbf{X}'\mathbf{A}\mathbf{X} = \frac{\partial}{\partial \mathbf{A}}tr[\mathbf{X}\mathbf{X}'\mathbf{A}] = [\mathbf{X}\mathbf{X}']' = \mathbf{X}\mathbf{X}'$, this implies

$$\begin{aligned}\frac{\partial l}{\partial \mu} &= 0 - 0 - \frac{1}{2}\left(\mathbf{\Sigma}^{-1}(\mathbf{y} - \mathbf{M}\mu)(-\mathbf{M}') + ((\mathbf{\Sigma}^{-1})'(\mathbf{y} - \mathbf{M}\mu)(-\mathbf{M}')\right) \\ &= -\frac{1}{2}\left(-2\mathbf{M}'\mathbf{\Sigma}^{-1}(\mathbf{y} - \mathbf{M}\mu)\right) \\ &= \mathbf{M}'\mathbf{\Sigma}^{-1}(\mathbf{y} - \mathbf{M}\mu).\end{aligned}$$

Setting equal to zero, this implies

$$\begin{aligned}0 &= \mathbf{M}'\hat{\mathbf{\Sigma}}^{-1}(\mathbf{y} - \hat{\mu}) \\ \Rightarrow 0 &= \mathbf{M}'\hat{\mathbf{\Sigma}}^{-1}\mathbf{y} - \mathbf{M}'\hat{\mathbf{\Sigma}}^{-1}\hat{\mu}.\end{aligned}$$

Therefore,

$$\hat{\mu} = (\mathbf{X}'\hat{\mathbf{\Sigma}}^{-1}\mathbf{M})^{-1}\mathbf{M}'\hat{\mathbf{\Sigma}}^{-1}\mathbf{y}.$$

Similarly,

$$\frac{\partial l}{\partial \mathbf{\Sigma}^{-1}} = 0 + \frac{N}{2}\mathbf{\Sigma} - \frac{1}{2}(\mathbf{y} - \mathbf{M}\mu)(\mathbf{y} - \mathbf{M}\mu)'.$$

Setting equal to zero, this implies

$$\begin{aligned}0 &= 0 + \frac{N}{2}\hat{\mathbf{\Sigma}} - \frac{1}{2}(\mathbf{y} - \mathbf{M}\hat{\mu})(\mathbf{y} - \mathbf{M}\hat{\mu})' \\ \Rightarrow \frac{N}{2}\hat{\mathbf{\Sigma}} &= \frac{1}{2}(\mathbf{y} - \mathbf{M}\hat{\mu})(\mathbf{y} - \mathbf{M}\hat{\mu})'.\end{aligned}$$

Therefore,

$$\hat{\mathbf{\Sigma}} = \frac{1}{N}(\mathbf{y} - \mathbf{M}\hat{\mu})(\mathbf{y} - \mathbf{M}\hat{\mu})'.$$

2. At least one second-order partial derivative is negative. The second-order partial derivative elements are:

$$\frac{\partial^2 l}{\partial \mu^2} = \frac{\partial}{\partial \mu}(\mathbf{M}'\mathbf{\Sigma}^{-1}\mathbf{y} - \mathbf{M}'\mathbf{\Sigma}^{-1}\mathbf{M}\mu) = -\mathbf{M}'\mathbf{\Sigma}^{-1}\mathbf{M} < 0,$$

since $\mathbf{M}'\sigma^{\mathbf{2}}_{\mathbf{level}}\mathbf{M} > 0$ $\mathbf{\Sigma} > 0$ and

$$\frac{\partial^2 l}{\partial \Sigma^2} = \frac{N}{2}\hat{\mathbf{\Sigma}} - \frac{1}{2}(\mathbf{y} - \mathbf{M}\hat{\mu})(\mathbf{y} - \mathbf{M}\hat{\mu})' = \frac{N}{2} - 0 = \frac{N}{2}$$

$$\frac{\partial^2 l}{\partial \Sigma \partial \mu} = \frac{\partial^2 l}{\partial \mu \partial \Sigma} = \frac{\partial l}{\partial \mu}(\frac{N}{2}\mathbf{\Sigma} - \frac{1}{2}(\mathbf{y} - \mathbf{M}\mu)(\mathbf{y} - \mathbf{M}\mu)') = -\frac{1}{2}(\mathbf{y} - \mathbf{M}\mu)(\mathbf{y} - \mathbf{M}\mu)') < 0$$

3. The Jacobian of the second-order partial derivative is positive. The Jacobian is:

$$\begin{vmatrix} \frac{\partial^2}{\partial \mu^2} l(\mu, \Sigma) & \frac{\partial^2}{\partial \mu \partial \Sigma} l(\mu, \Sigma) \\ \frac{\partial^2}{\partial \Sigma \partial \theta} l(\mu, \Sigma) & \frac{\partial^2}{\partial \Sigma^2} l(\mu, \Sigma) \end{vmatrix} = \begin{vmatrix} -\mathbf{X}'\mathbf{\Sigma}^{-1}\mathbf{X} & -\frac{1}{2}(\mathbf{y} - \mathbf{X}\mu)(\mathbf{y} - \mathbf{X}\mu)') \\ -\frac{1}{2}(\mathbf{y} - \mathbf{X}\mu)(\mathbf{y} - \mathbf{X}\mu)') & \frac{N}{2} \end{vmatrix}$$

$$= \frac{-NX\Sigma^{-1}X}{2} - (\frac{1}{2}(\mathbf{y} - \mathbf{X}\mu)(\mathbf{y} - \mathbf{X}\mu)'))^2 > 0$$

Sampling Variances.

The standard error of $\hat{\mu}$ is the square root of the variance of $\hat{\mu}$. That is

$$s.e.(\hat{\mu}) = \sqrt{Var(\hat{\mu})}$$

$$\begin{aligned} Var[\hat{\mu}] &= Var[(\mathbf{M}'\mathbf{\Sigma}^{-1}\mathbf{M})^{-1}\mathbf{M}'\mathbf{\Sigma}^{-1}\mathbf{y}] \\ &= Var[(\mathbf{M}'\mathbf{\Sigma}^{-1}\mathbf{M})^{-1}\mathbf{M}'\mathbf{\Sigma}^{-1}(\mathbf{M}\mu + \varepsilon)] \\ &= Var[(\mathbf{M}'\mathbf{\Sigma}^{-1}\mathbf{M})^{-1}\mathbf{M}'\mathbf{\Sigma}^{-1}\mathbf{M}\mu + (\mathbf{M}'\mathbf{\Sigma}^{\mathbf{-1}}\mathbf{M})^{\mathbf{-1}}\mathbf{M}'\mathbf{\Sigma}^{\mathbf{-1}}\varepsilon] \\ &= Var[(\mathbf{M}'\mathbf{\Sigma}^{-1}\mathbf{M})^{-1}\mathbf{M}'\mathbf{\Sigma}^{-1}\mathbf{M}\mu] + Var[(\mathbf{M}'\mathbf{\Sigma}^{-1}\mathbf{M})^{-1}\mathbf{M}'\mathbf{\Sigma}^{-1}\varepsilon] \end{aligned}$$

such that $Var(\mu) = 0$. This implies

$= Var[0 + (\mathbf{M'\Sigma}^{-1}\mathbf{M})^{-1}\mathbf{M'\Sigma^{-1}}\varepsilon]$

$= Var[(\mathbf{M'\Sigma}^{-1}\mathbf{M})^{-1}\mathbf{M'\Sigma^{-1}}\varepsilon]$

$= ((\mathbf{M'\Sigma}^{-1}\mathbf{M})^{-1}\mathbf{M'\Sigma^{-1}})Var[\varepsilon](\mathbf{M'\Sigma}^{-1}\mathbf{M})^{-1}\mathbf{M'\Sigma^{-1}})'$

$= ((\mathbf{M'\Sigma}^{-1}\mathbf{M})^{-1}\mathbf{M'\Sigma^{-1}})\mathbf{\Sigma}((\mathbf{M'\Sigma}^{-1}\mathbf{M})^{-1}\mathbf{M'\Sigma^{-1}})'$

$= ((\mathbf{M'\Sigma}^{-1}\mathbf{M})^{-1}\mathbf{M'})(\mathbf{\Sigma^{-1}\Sigma})((\mathbf{M'\Sigma}^{-1}\mathbf{M})^{-1}\mathbf{M'\Sigma^{-1}})'$

such that Σ is a diagonal matrix and $\Sigma^{-1}\Sigma = I_{N\times N}$. This implies

$= (\mathbf{M'\Sigma}^{-1}\mathbf{M})^{-1}\mathbf{M'}I_{N\times N}((\mathbf{M'\Sigma}^{-1}\mathbf{M})^{-1}\mathbf{M'\Sigma^{-1}})'$

$= (\mathbf{M'\Sigma}^{-1}\mathbf{M})^{-1}\mathbf{M'}((\mathbf{M'\Sigma}^{-1}\mathbf{M})^{-1}\mathbf{M'\Sigma^{-1}})'$

$= (\mathbf{M'\Sigma}^{-1}\mathbf{M})^{-1}\mathbf{M'}(\mathbf{\Sigma'})^{\mathbf{-1}}\mathbf{M}((\mathbf{M'\Sigma}^{-1}\mathbf{M})')^{-1}$

since $\mathbf{\Sigma}$ is a diagonal matrix and symmetric such that $\Sigma' = \Sigma$. This implies

$= [(\mathbf{M'\Sigma}^{-1}\mathbf{M})^{-1}\mathbf{M'\Sigma^{-1}M}]((\mathbf{M'\Sigma}^{-1}\mathbf{M})')^{-1}$

$= ((\mathbf{M'\Sigma}^{-1}\mathbf{M})')^{-1}$

since $(\mathbf{XA})' = \mathbf{A'X'}$ and $(\mathbf{A'})' = \mathbf{A}$. This implies

$= (\mathbf{M'}(\mathbf{\Sigma'})^{-1}\mathbf{M})^{-1}$

$= (\mathbf{M'\Sigma}^{-1}\mathbf{M})^{-1}$

$= \mathbf{M}^{-1}\mathbf{\Sigma}(\mathbf{M'})^{-1}$

$= \mathbf{\Sigma M}^{-1}I(\mathbf{M'})^{-1}$

$= \mathbf{\Sigma M}^{-1}(\mathbf{M'})^{-1}$

$= \mathbf{\Sigma M}^{-1}(\mathbf{M'})^{-1}$

$= \mathbf{\Sigma}(\mathbf{M'M})^{-1}$

Therefore,

$$s.e.(\hat{\mu}) = \sqrt{Var(\hat{\mu})} = \sqrt{\mathbf{\Sigma}(\mathbf{M'M})^{-1}}$$

Appendix B. Power Tables.
